SWAT Seasonal plant growth simulation

Tropics

Rainfall

Controlling factors

Realistic representation of
seasonal growth dynamics

Temperate

Temperature

SWAT-T Goal - improve vegetation growth module in the Tropics

LAI

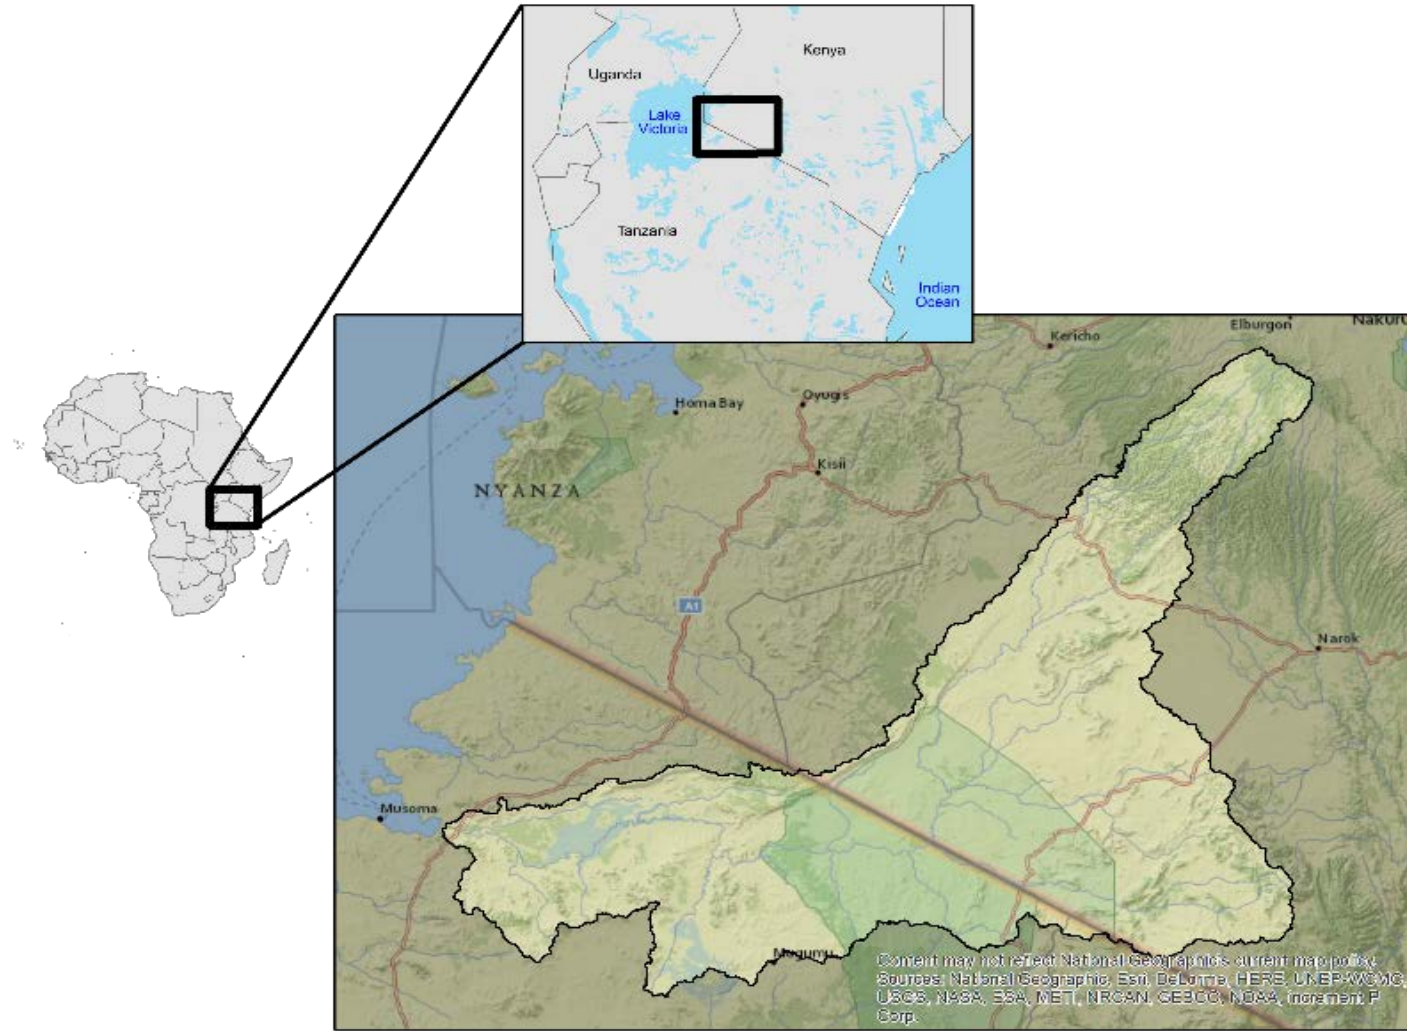

How does SWAT-T work in the Tropics?

Triggers a new growing season

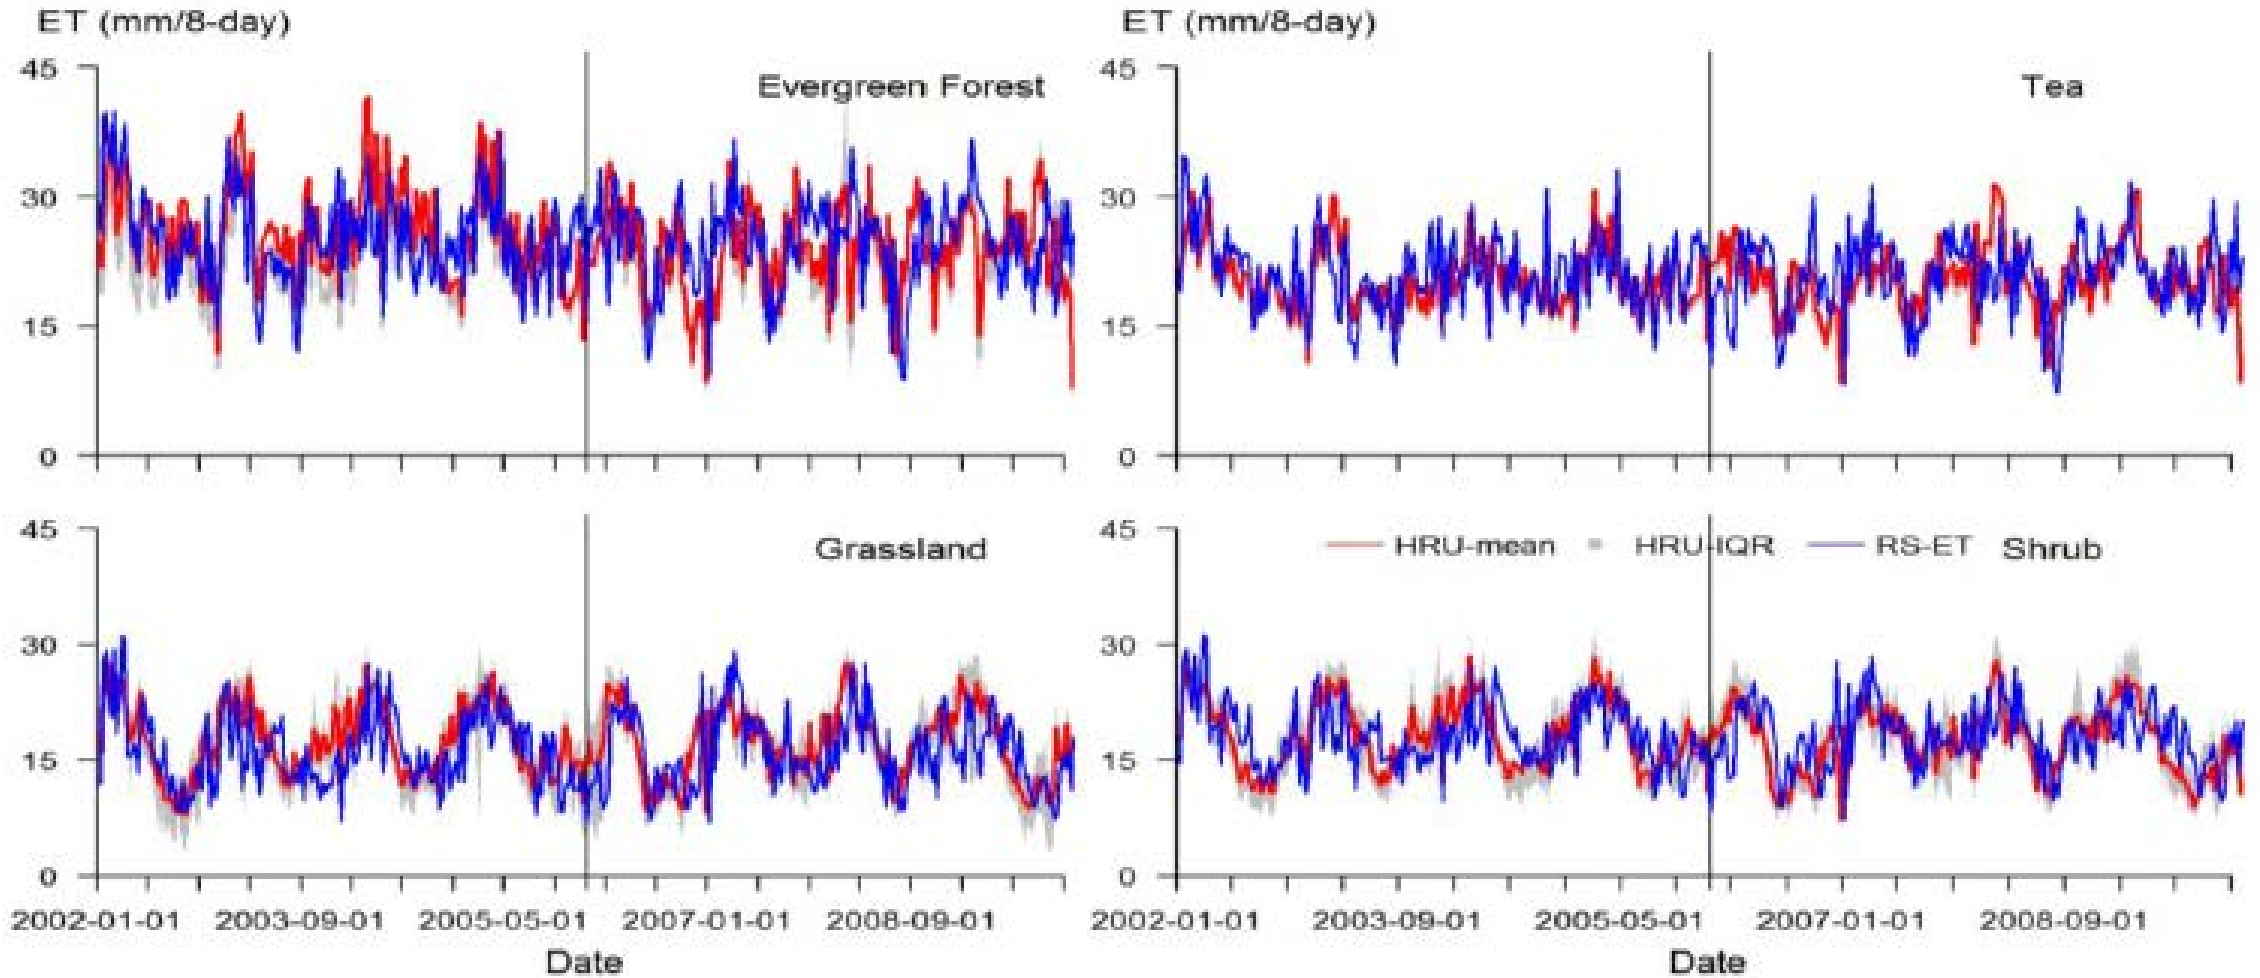

Mara basin, Kenya & Tanzania

LAI Comparison with MODIS LAI

ET Comparison with MODIS ET

SEBAL Algorithm for RS data

$$R_n - \lambda E_v - G - H_v = 0$$

SEBAL needs:

- Visible Bands, NIR
- Thermal Band

SEBAL implementation in python = pySEBAL

SEBAL

- Input:
 - Landsat (30 m)
 - Meteodata (Temp, Wind, etc.)
 - DEM
- Output:
 - ETact
 - ETpot
 - ETO (reference ET)
 - Tpot
 - Tact
 - Soil moisture top soil
 - Soil moisture root zone
 - Biomass Production

pySEBAL can now use VIIRS/PROBA-V

Landsat -7 and 8, 30 m, 8 days

Thermal

VIIRS, 375 m, 1 day

Visible

Proba-V, 100 m, 5 days

Thermal Sharpening:

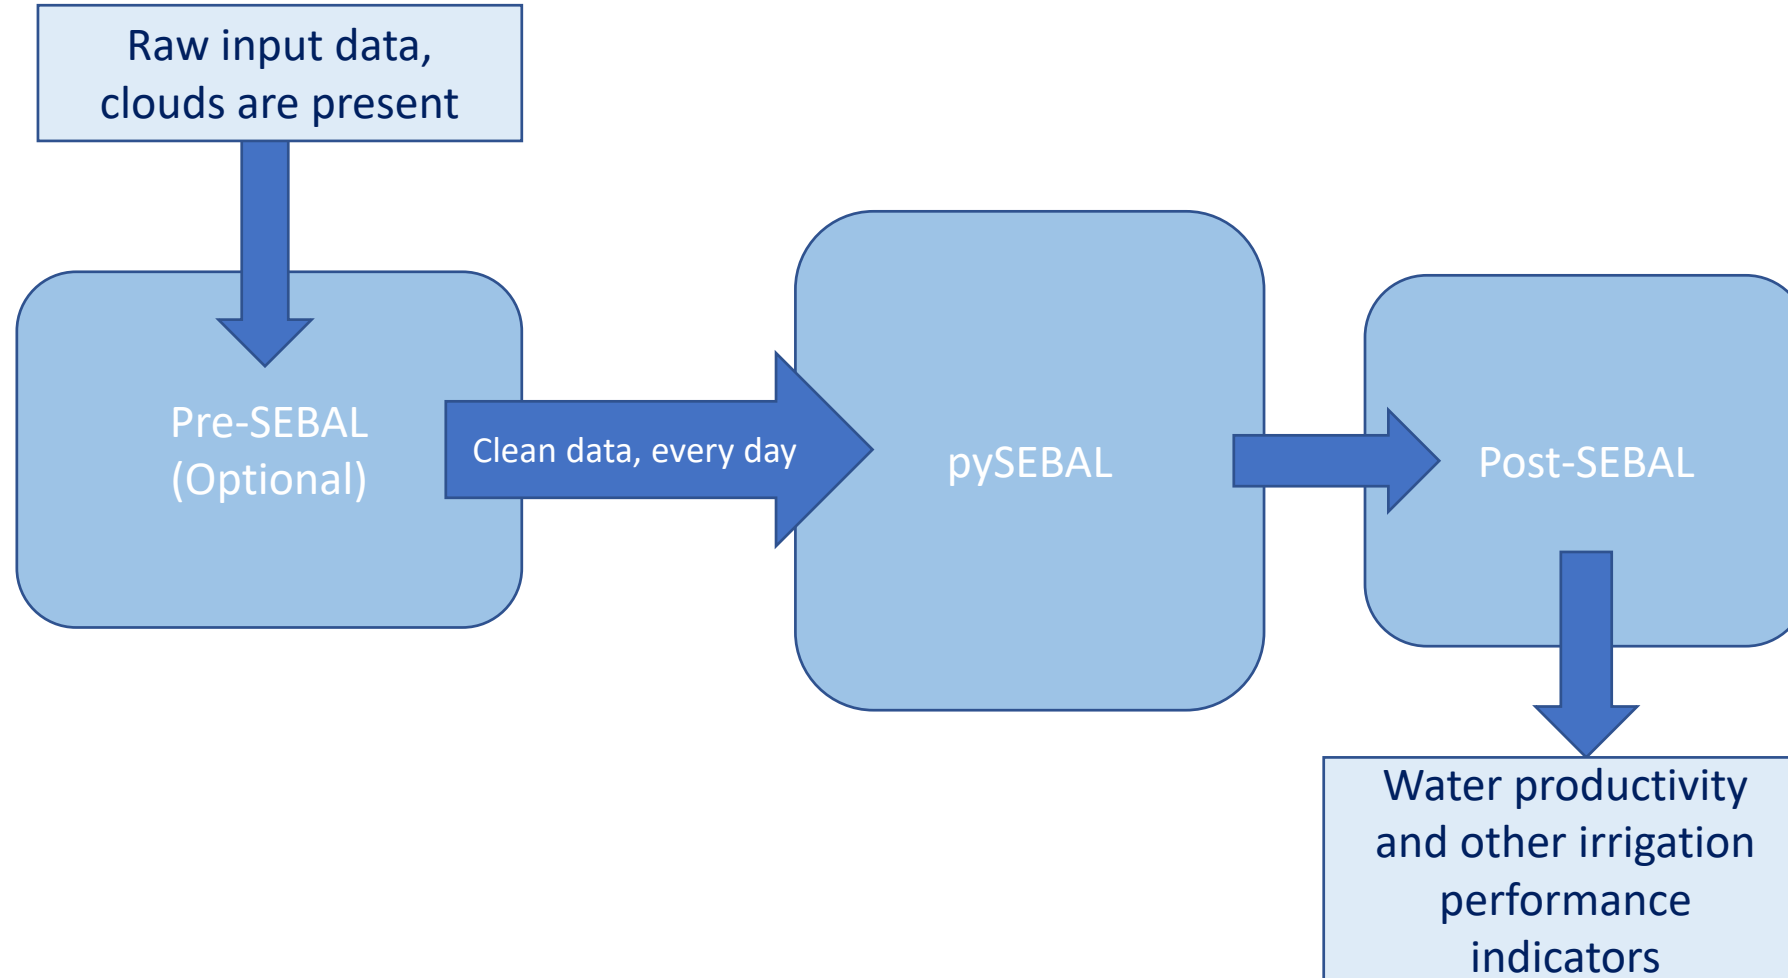

Downscale VIIRS thermal band (375m) to 100m by using NDVI from PROBA-V

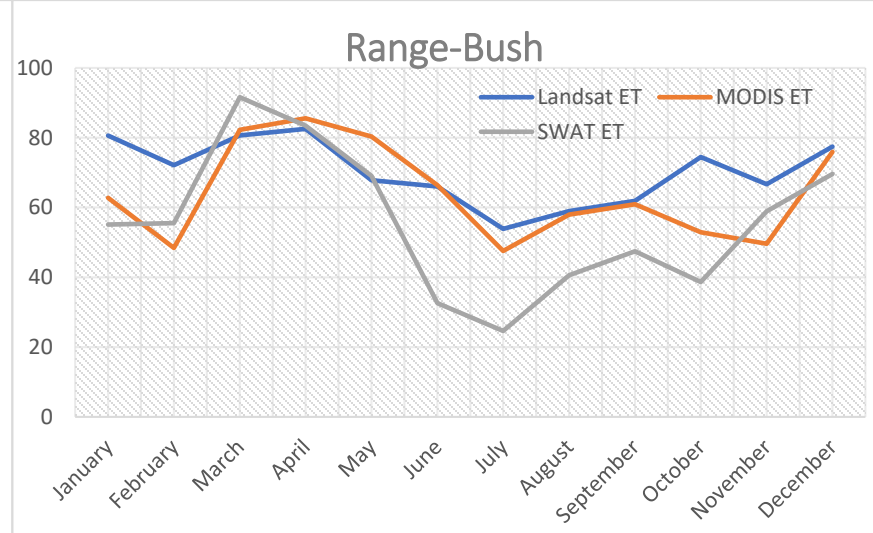

LS run: 30m 8-daily

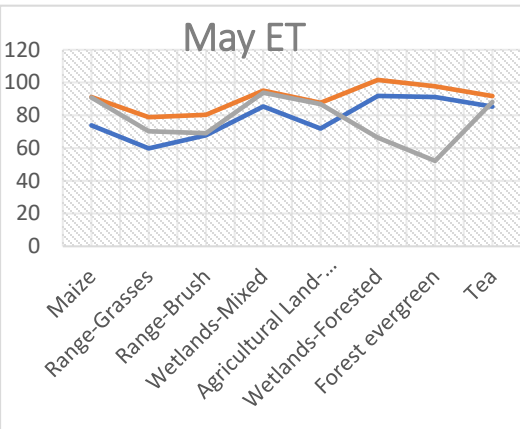

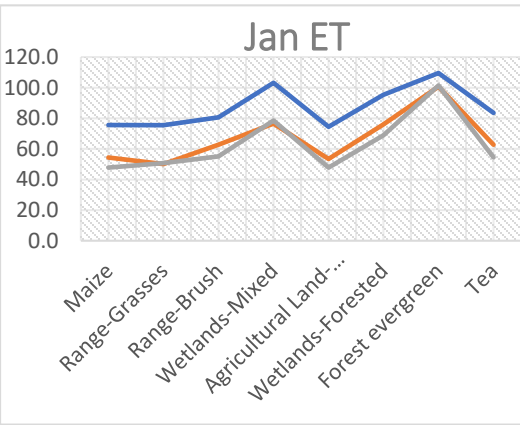

PROBA-V/VIIRS run: 100m daily

pySEBAL developments

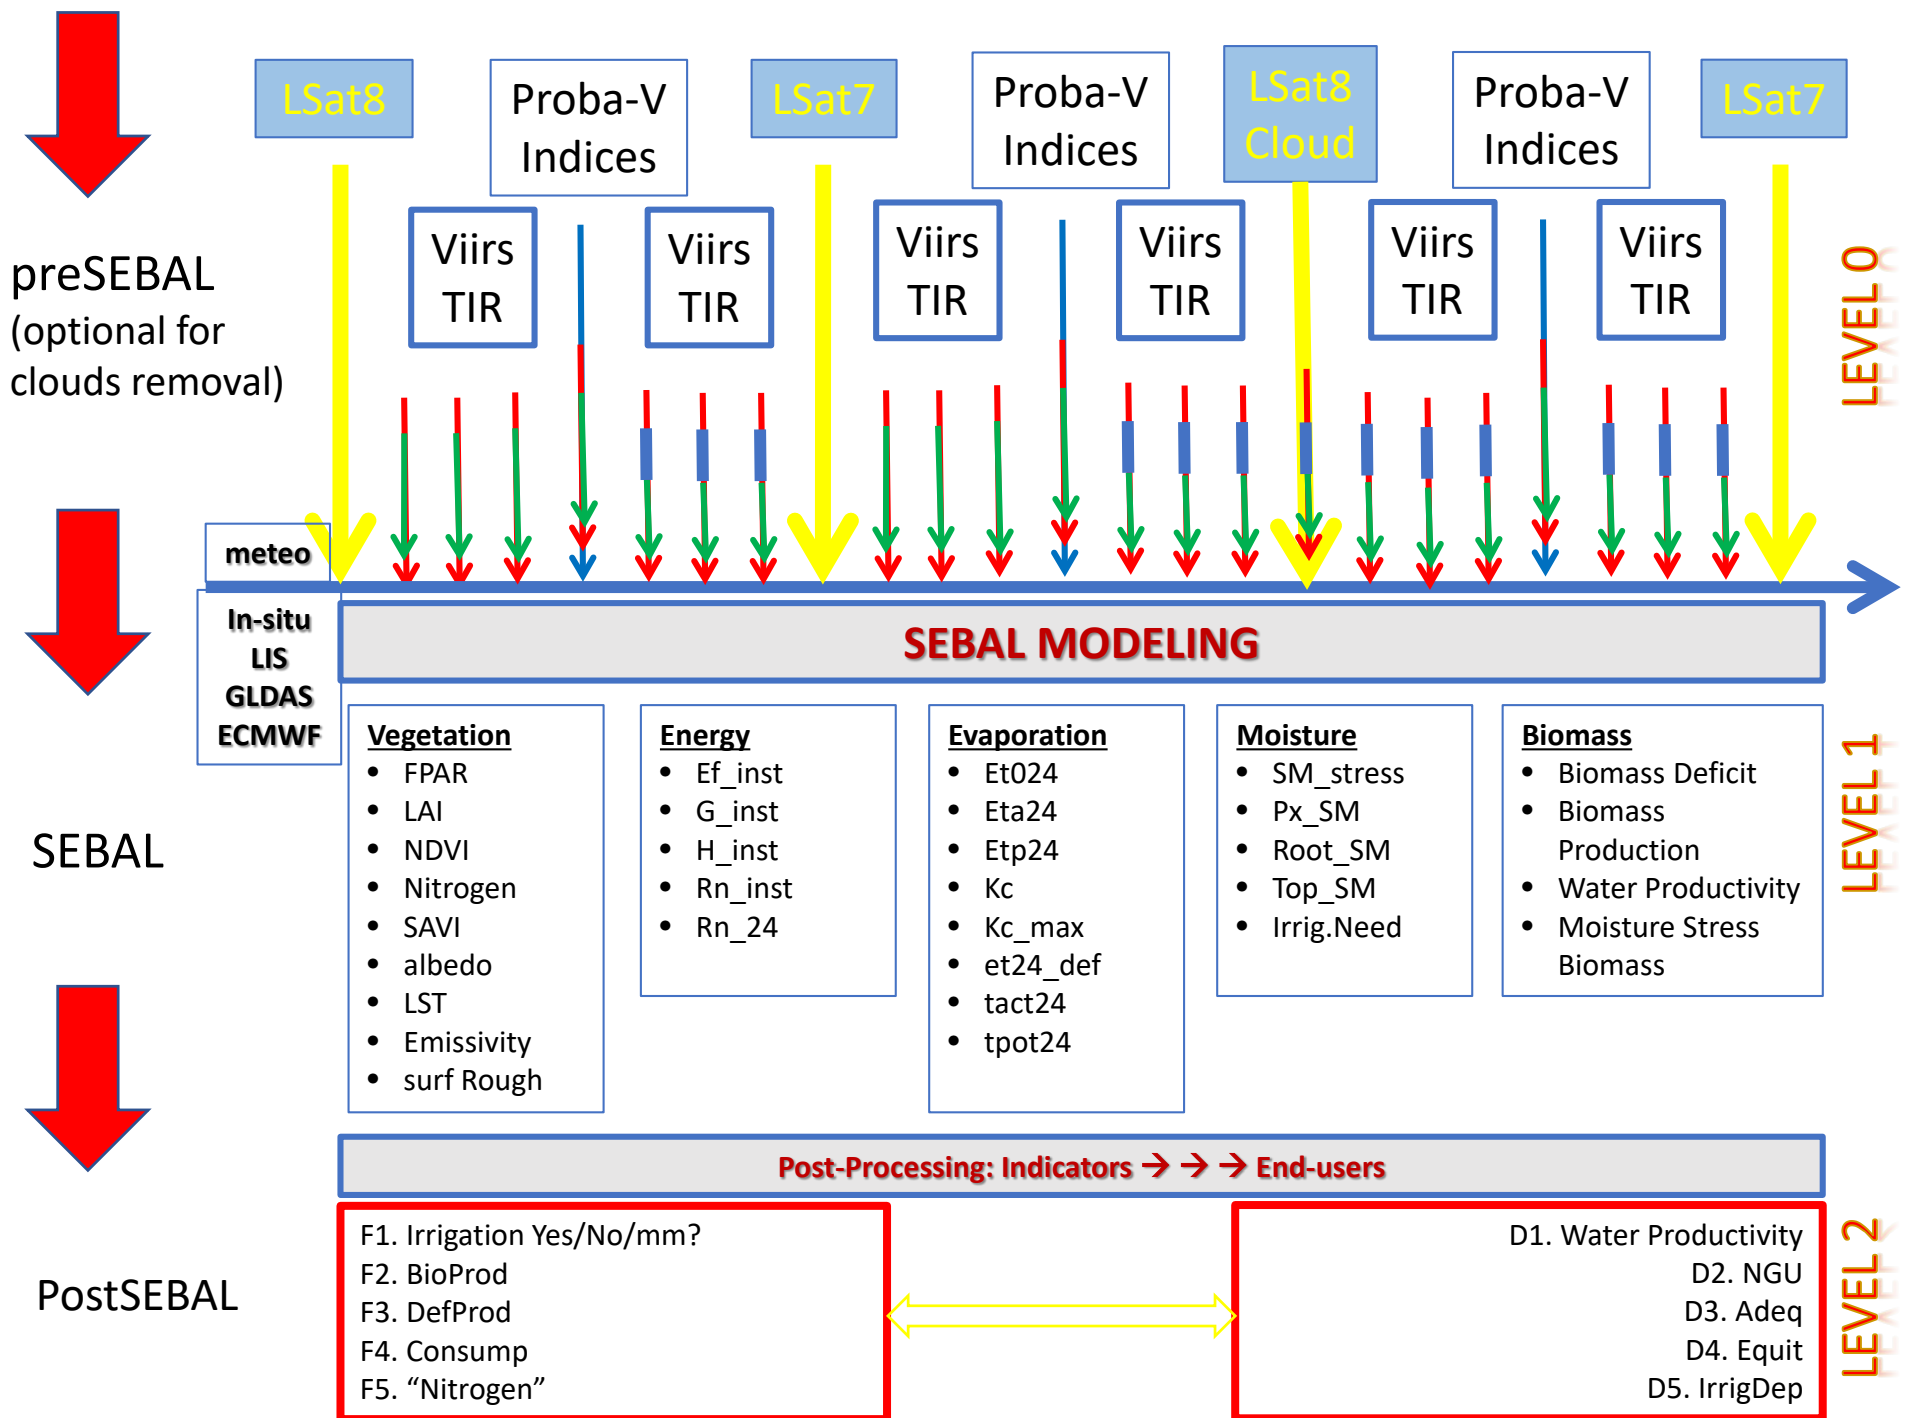

SWAT-T comparison with MODIS & Landsat

ongoing work

- Checking on Biomass, LAI and yield simulation in SWAT-T against RS
- SWAT-T water productivity mapping and compare with pySEBAL
- Water accounting from SWAT-T and RS products
