- Impact of surface-groundwater exchange fluxes
- Watershed soundness assessment
- Summary and conclusions

Introduction (Why this study?)

- With increasing concerns surrounding the global climate change, there has been growing interests in the potential impacts to groundwater. It is expected that the predicted global changes in temperature and precipitation will alter the regional climates and water resources systems.
- Therefore, the accurate understanding of hydrologic processes occurring in basin is important to formulate the water resources policies, planning and management decisions in the region.
- We need to simulate the components of hydrologic cycle to determine the impacts of land use changes, groundwater use, and dam operation of river basin on water resources policies, planning and management.
- The purpose of this study is to investigate the impacts of surface water and groundwater interaction on water balance and groundwater recharge for <u>watershed soundness assessment of Han River basin</u> (34,148 km²) in South Korea by SWAT modeling.

5 Major River basins of South Korea

- 5 Major river basins in our country (Han, Geum, Yeongsan, Seomjin, and Nakdong)
- The global warming is now warning the management of streamflow (intensify drought and flood)
- Need to evaluate the availability water resource by water balance analysis
- From the evaluation, find out some insight and prepare proper direction for water management system

Dams & Diversions of South Korea

- At present, we have 20 multipurpose dams and 19 multifunction weirs in South Korea.
- They have been successfully managed by both Korea Water Resources Corporation (K-water) and Korea Hydro & Nuclear Power Co. Ltd. (KHNP) to fulfill water demands, flood control and hydropower generation.
- Korea needs fundamental countermeasures to mitigate damages from repetitive floods and droughts caused by climate change.

Research procedure

Observed Data	GIS Data	Multipurpose Dam Data						
 Weather data (1984-2014) Evapotranspiration (2009-2013) Soil moisture (2009-2013) Groundwater level (2009-2013) 	 DEM, Soil, Land use 	 4 multipurpose water supply dams (1984-2 Dam inflow, storage, release 3 multifunction weirs (2012-2014) Dam inflow, storage, release 						
Iodel Process Dynamics								
	SWAT Mo	del						
 Model run (1984-2014) 	Surface Processes							
• Warm-up (1984)	 Vertical water budget : infiltration, evapotranspiration 							
Calibration (2005-2009)	 Horizontal water transfer: surface runoff 							
and validation (2010-2014)	Soil Water Dynamics							
 <u>Dam & weir inflow</u> <u>Dam & weir storage</u> 		budget : percolation, soil water storage,						
• <u>Evapotranspiration</u>	 Horizontal water transfer: lateral flow 							
• <u>Soil moisture</u>	Groundwater Dynamics							
 <u>Groundwater level variation</u> Dam operation (2005-2014) 	 Vertical water budget : groundwater revap, groundwater recharge, Horizontal water transfer: return flow 							

Model Results

Analysis of Water Balance

- Vertical water budget and horizontal water transfers
- Surface-groundwater exchange fluxes

Watershed Soundness Assessment

- Normalized metric value \rightarrow sub-index
- Watershed health index

SWAT model (Soil and Water Assessment Tool)

Water balance

$$SW_{t} = SW_{0} + \sum_{i=1}^{t} (R_{day} - Q_{surf} - E_{a} - W_{seep} - Q_{gW})$$

 $\begin{array}{ll} SW_t &= Final \ soil \ water \ content \ (mm) \\ SW_0 &= Initial \ soil \ water \ content \ on \ day \ i \ (mm) \\ R_{day} &= Amount \ of \ precipitation \ on \ day \ i \ (mm) \\ Q_{surf} &= Amount \ of \ surface \ runoff \ on \ day \ i \ (mm) \\ E_a &= Amount \ of \ evapotranspiration \ on \ day \ i \ (mm) \\ W_{seep} &= Amount \ of \ water \ entering \ the \ vadose \ zone \\ from \ the \ soil \ profile \ on \ day \ i \ (mm) \\ Q_{aw} &= Amount \ of \ return \ flow \ on \ day \ i \ (mm) \end{array}$

Reservoir

$$V = V_{stored} + V_{flowin} - V_{flowout} + V_{pcp} - V_{evap} - V_{seep}$$

V = volume of water in the impoundment at the end of the day (m3H2O) $V_{stored} = volume of water stored in the water body at the beginning of the day (m3 H2O)$ $V_{flowin} = volume of water entering the water body during the day (m3 H2O)$ $V_{flwout} = volume of water flowing out of the water body during the day (m3 H2O)$ $V_{pcp} = volume of precipitation falling on the water body during the day (m3 H2O)$ $V_{evap} = volume of water removed from the water body by evaporation during the day (m3 H2O)$ $V_{seep} = volume of water lost from the water body by seepage (m3 H2O).$

Summary and conclusions

- In this study, the surface water and groundwater interaction modeling of Han River basin in South Korea was performed using SWAT model.
 - ✓ The SWAT was calibrated using 4 measured dam and 3 weir operation data (storage and inflow) and with spatial hydrologic component data (evapotranspiration and soil moisture).
 - ✓ The SWAT model was used in the analysis of the water balance by vertical water budget (INFILT, ET, PERCOL, SW, REVAP and GR) and the horizontal water transfers (SQ, LQ and RQ).
- During dry season (Oct. to May), the evapotranspiration and return flow was 29% and 10% higher compared to those of wet season. So, they should be treated as important factors for the whole hydrological cycle.
- The period of (a) February to August was characterized by net inflow of <u>infiltration into</u> <u>the groundwater</u>. For the (b) September to January period, the groundwater flow into the <u>river</u> of the basin showed net outflow. The whole period was nearly balanced by the net flux. The groundwater recharge was found as an important factor to show the same pattern of exchange fluxes during the hydrological year.
- The results of this research is planned to investigate the impact of climate and land use change scenarios on water resources and to assess the soundness and vulnerability of watershed regions.

Thank you
