Ethiopia

INTRODUCTION

- The natural environment is under tremendous stress as a consequence of various demands of increasing population.
- Temporal and spatial patterns of precipitation and extreme flows have been changing in the recent past.
- Global water balance is highly influenced...
- Increased earth and sea surface temp., melting of polar ice, rise in average global ocean level...

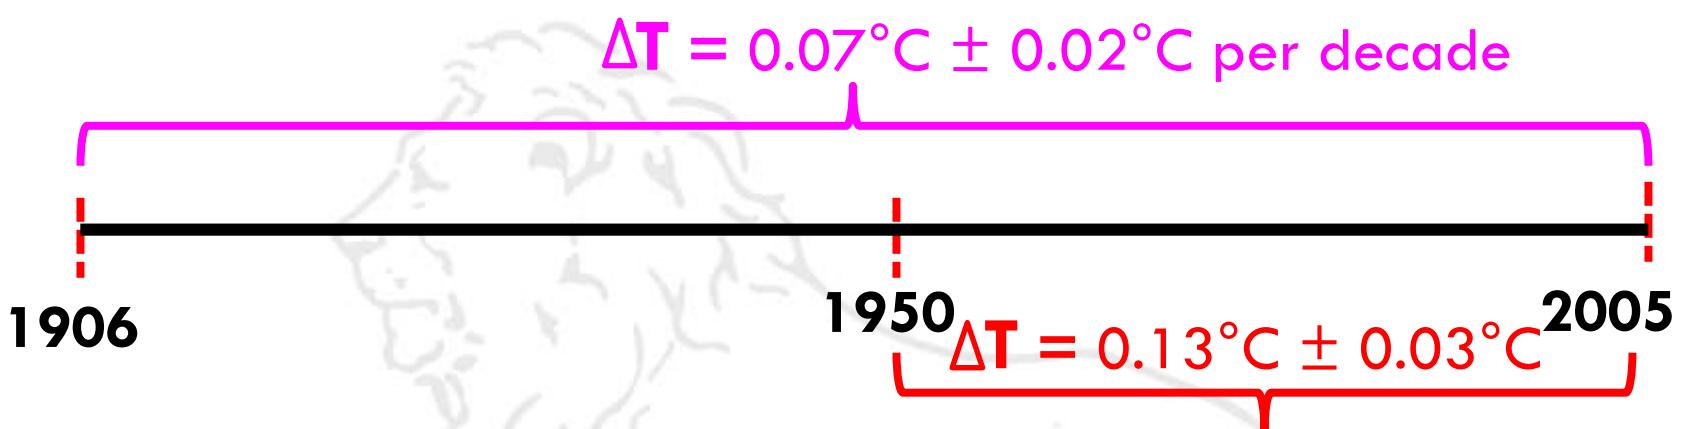

(Loaiciga et al., 1996; Singh et al., 1997; Barnett et al., 2005; Steele-Dunne et al., 2008; IPCC, 2007)

Introduction...

- Avg. temp. rise of $0.6 \pm 0.2^{\circ}\text{C}$ (1860-2000) versus $0.74^{\circ}\text{C} \pm 0.18^{\circ}\text{C}$ (1906-2000) (IPCC, 2001; 2007)

$$\Delta T = 0.07^{\circ}\text{C} \pm 0.02^{\circ}\text{C} \text{ per decade}$$

- Anthropogenic induced land use/cover changes have transformed $1/3^{\text{rd}}$ - $1/4^{\text{th}}$ of ice-free surface of our planet (Vitousek, 1994; Vitousek et al., 1997).
- Land use/land cover changes significantly altered bulk water yield from the watershed.

Introduction...

- Land use changes are significant in tropical regions (Piao et al. 2007).
- Currently, 1/4th of the population of Africa is facing high water stress and this magnitude is expected to increase (2-3 fold) in the next 40 years (Boko et al., 2007)
- Adaptation mechanisms developed by African farmers are not sufficient enough to cope up with current and future climate variability (IPCC, 2007)

Introduction...

- The sub-Saharan region of Africa has been challenged by both man-made and natural stresses ([Tadross et al., 2005](#); [You and Ringler, 2010](#)).
- Key Features - prolonged drought
 - severe and unprecedented flood
 - poor economic developments
 - poor institutional developments
- Ethiopia is a victim of such global challenges
- Example: **48 flood and 12 drought events over the last Century** ([EM-DAT, 2010](#)).

Introduction...

Ethiopia: Agricultural sector accounts

- 45% of the country's GDP
- 85% of the export revenue
- Employs 80% of labour force.
- Major source of subsistence and income for majority of the rural population.
- Agricultural production is mainly rain-fed.

Introduction...

- Owing to limited data availability, little attempt has been made, in the past, to understand the watershed dynamics of Ethiopian basins in response to changing climate and catchment conditions.
- The Rift Valley lakes and rivers system of Ethiopia has undergone major changes in recent past.
- Agricultural, water supply, and hydropower sectors are affected by variable climate patterns.

Key Objectives

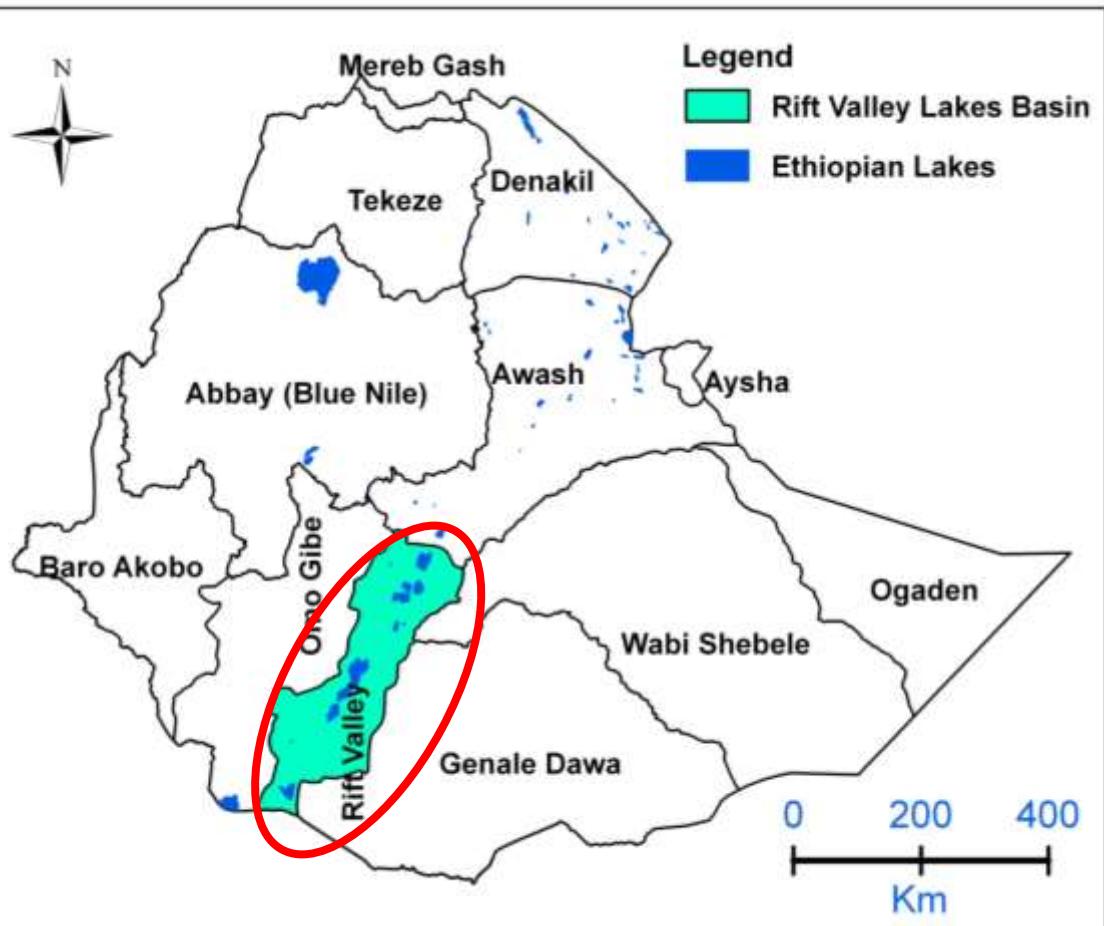

- Explore the impact of large scale present and future climatic variables under different greenhouse gas forcing on local climate at Rift Valley lakes basin of Ethiopia.
- Simulate runoff at desired locations using bias corrected precipitation and temperature in two snow free, agricultural watersheds in the basin.
- Forecast the likely future climate implications in the basin.

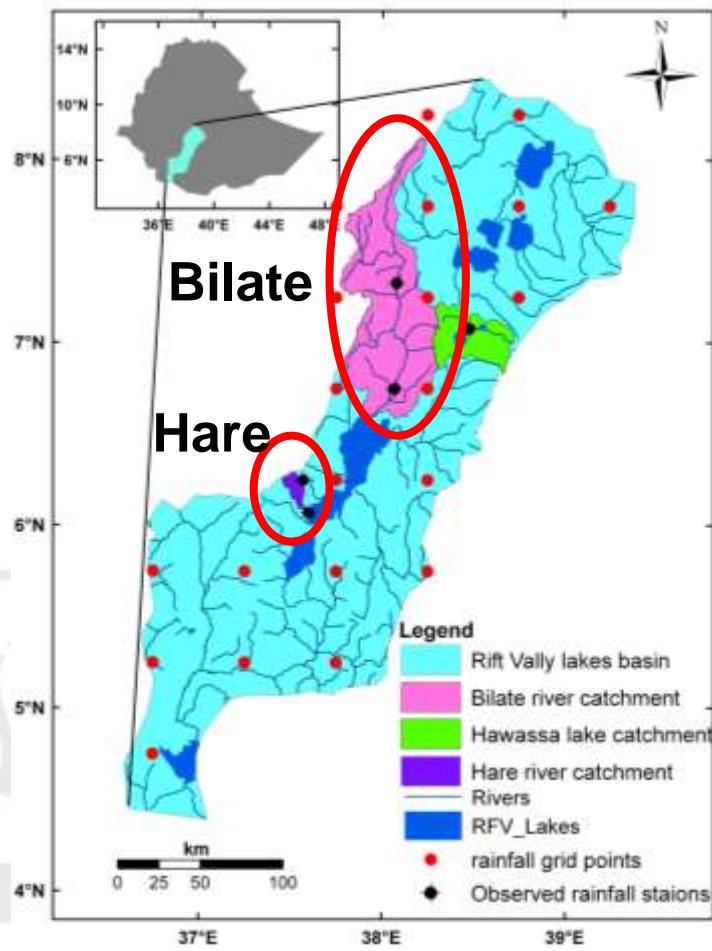

STUDY AREA

- The study mainly focuses on Rift Valley lakes Basin of Ethiopia.
- **Geog. location:** $4^{\circ}24'29''$ to $8^{\circ}26'38''$ N latitude and $36^{\circ}35'45''$ to $39^{\circ}23'31''$ E longitude.
- **Mean annual rainfall:** 600-1220 mm
- **Temperature:** Avg. temp. varies from 10.3°C (min.) to 30.6°C (max.)
- **Climate Condition:** sub-humid to moderate tropical semi-arid.
- **Gemorphology:** lowland plateau & escarpments
- **Study Watersheds:** Bilate (5330 km^2) and Hare (166.5 km^2)

River Basins of Ethiopia & Study Watersheds

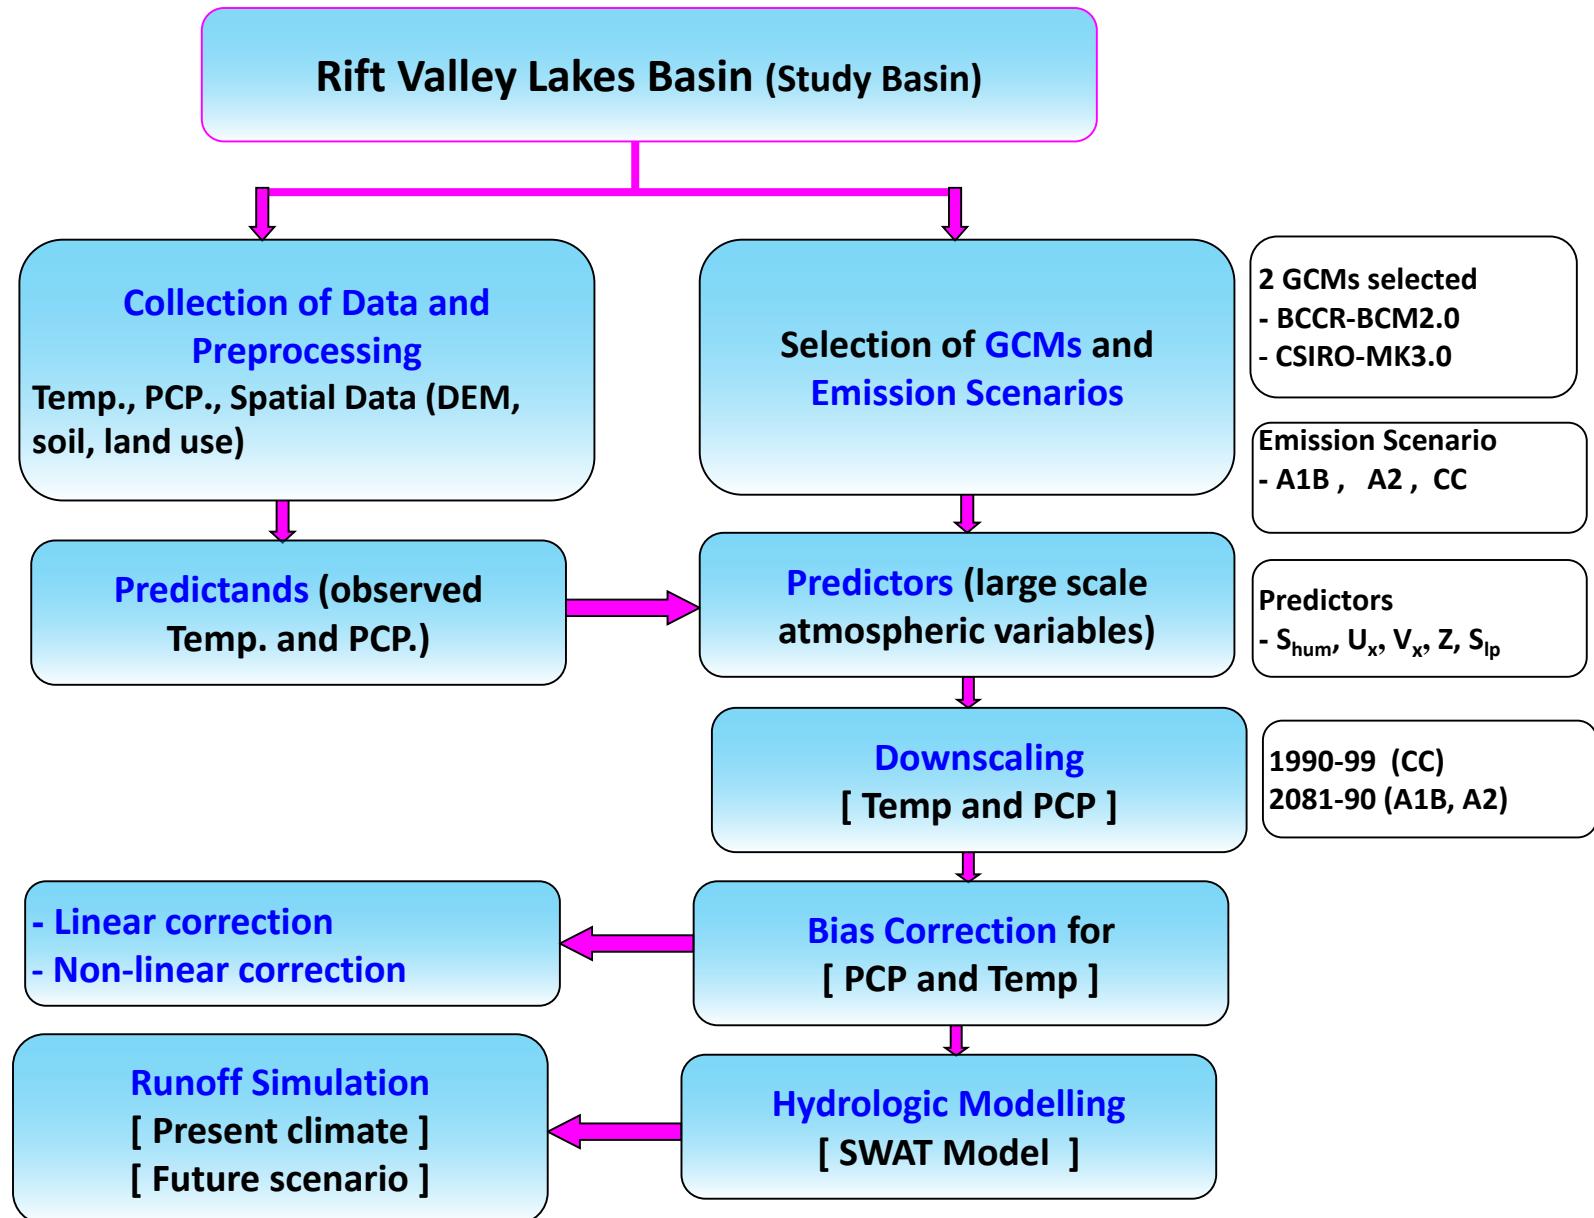

12 major river Basins

Bilate (5330 km^2) and
Hare (166.5 km^2)

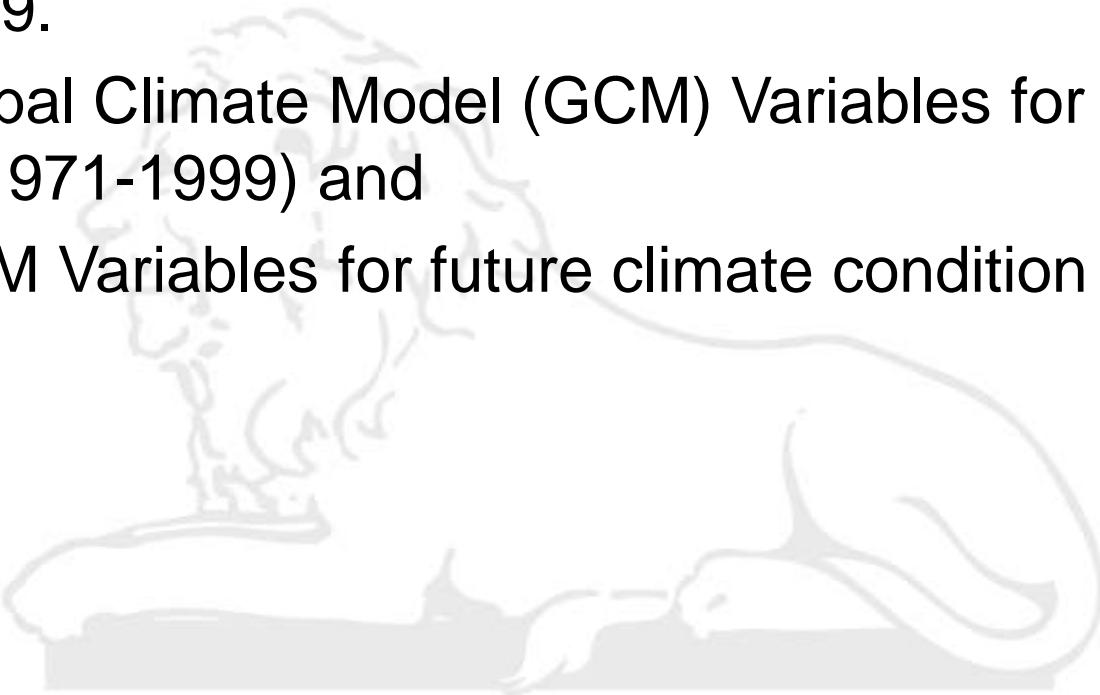

Methodology

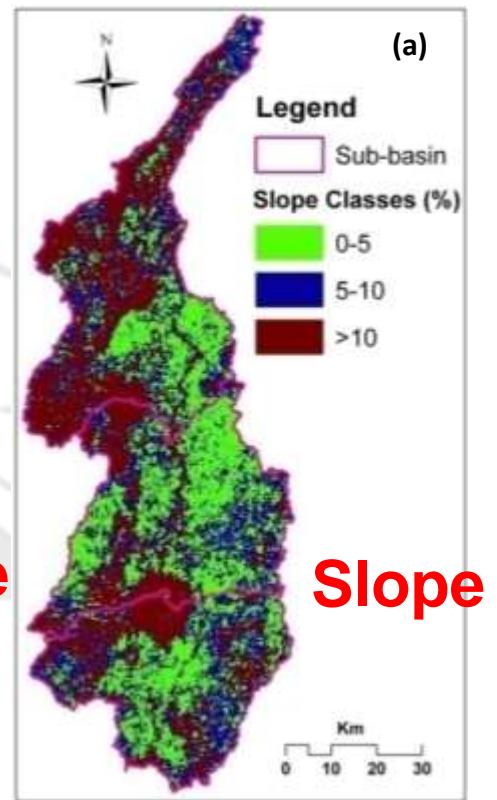

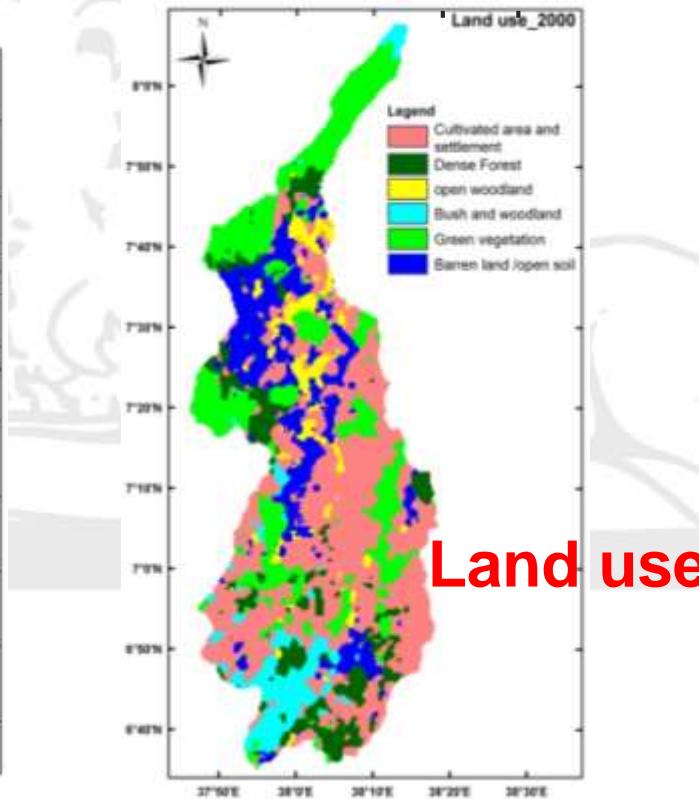

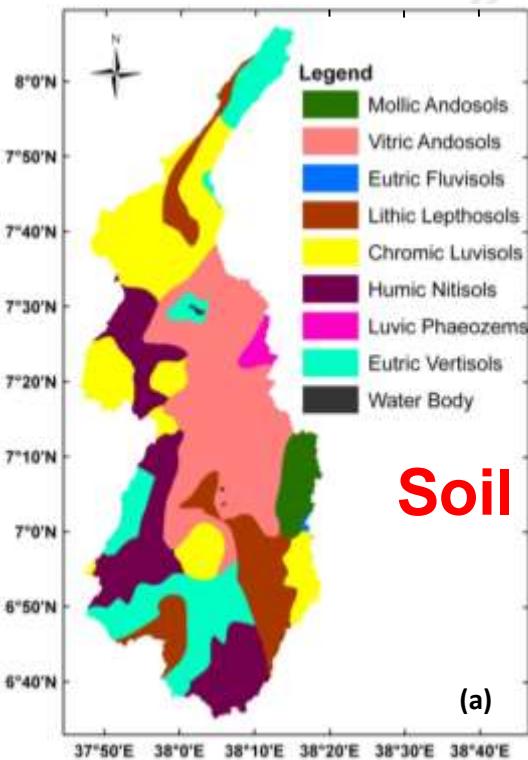

Dataset Used

- Observed daily precipitation and temperature data from 1980-2009.
- Daily Global Climate Model (GCM) Variables for current climate (1971-1999) and
- Daily GCM Variables for future climate condition (2081-2090).

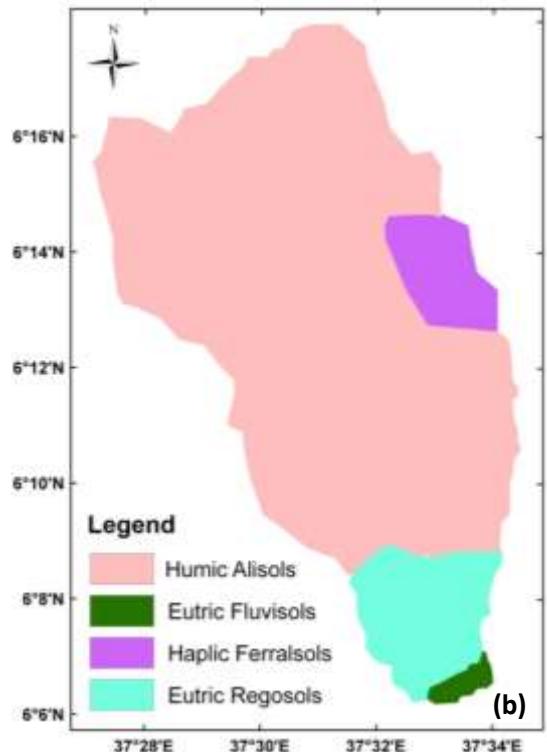

Data Used (Bilate and Hare watersheds)

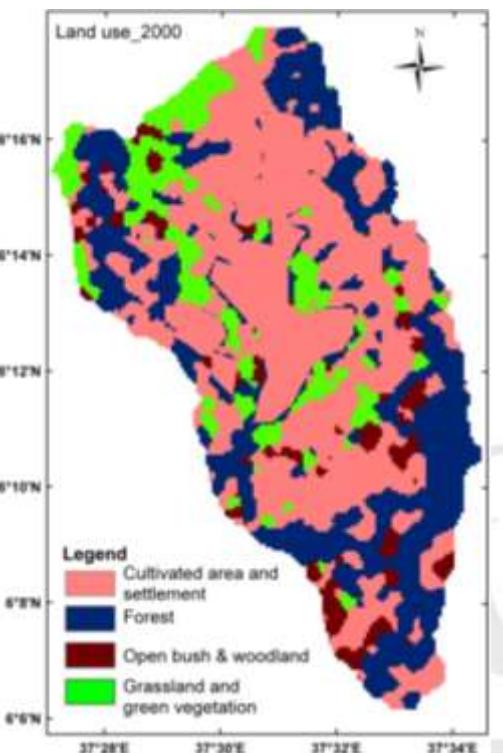

- Topographic Data (90m SRTM DEMs)
- Hydrometeorological Data (Daily RF, Temp., RH, Sunshine and Streamflow)
- Soil Data (FAO soil data); Land Use Data (Landsat image)

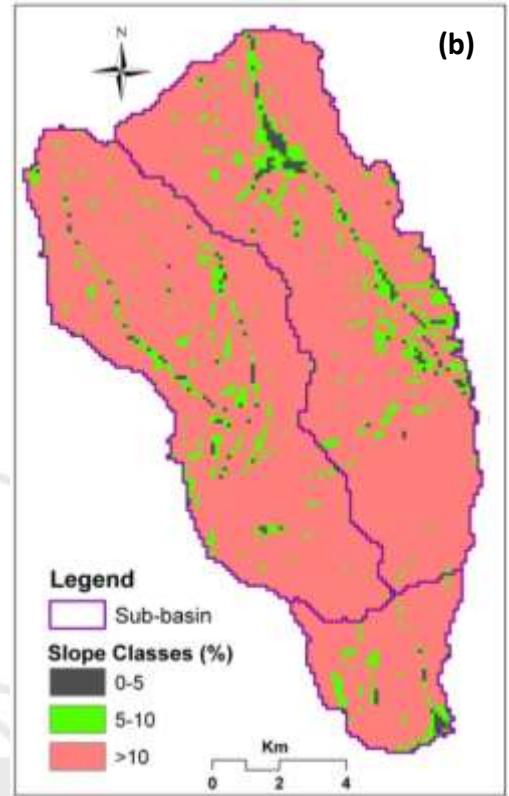

Soil Land use and Slope classes

Slope

GCMs Selected and Scenario Used

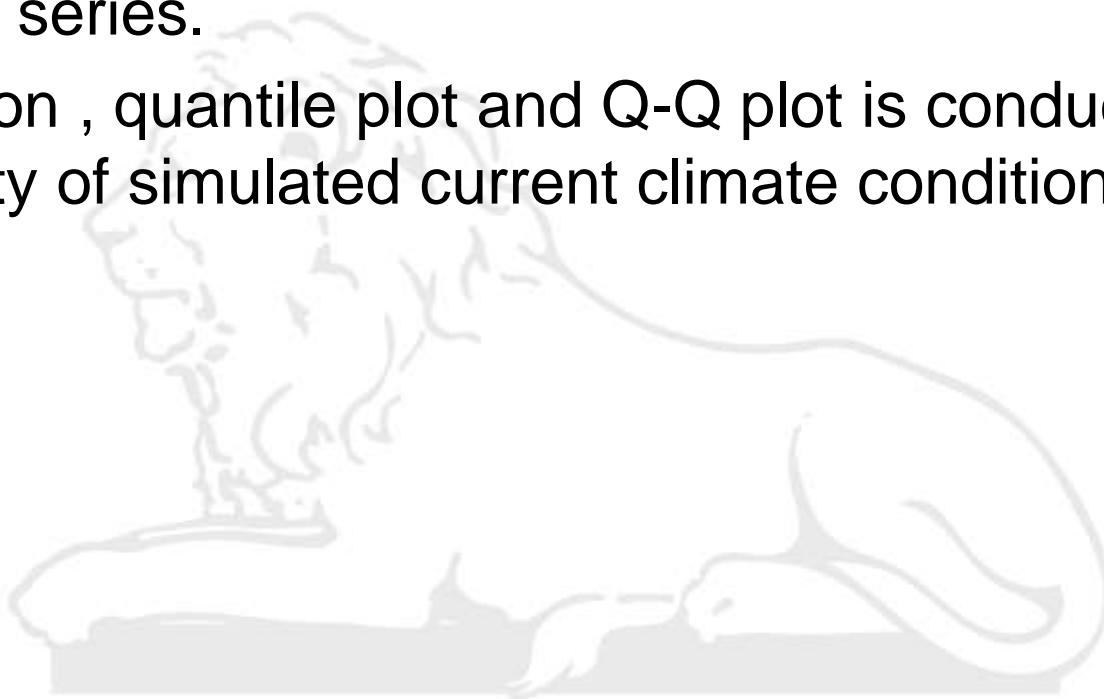

- **BCCR-BCM2.0** (Bjerknes Center for Climate Research Version 2.0 of Norway)
 - Atmospheric resolution of T63 ($1.9^\circ \times 1.9^\circ$)
 - Oceanic resolution of $0.5^\circ - 1.5^\circ \times 1.5^\circ$
- **CSIRO-MK3.0** (Commonwealth Scientific and Industrial Research Organization of Australia)
 - Atmospheric resolution of T63 ($1.9^\circ \times 1.9^\circ$)
 - Oceanic resolution of $0.9^\circ \times 1.9^\circ$.
- **Emission Scenarios Used:** A1B, A2 and Current Climate condition

A1B – medium forcing, CO₂ conc. 720 ppm in 2100 (Balanced World)
A2 – high forcing , CO₂ conc. 820ppm in 2100 (Heterogeneous World)

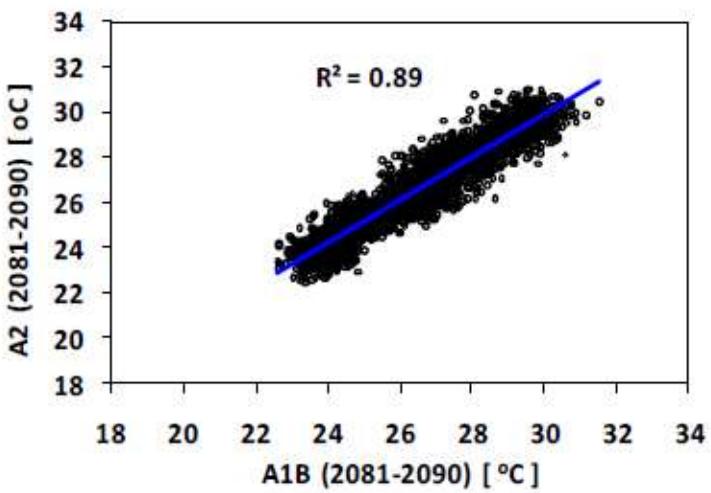

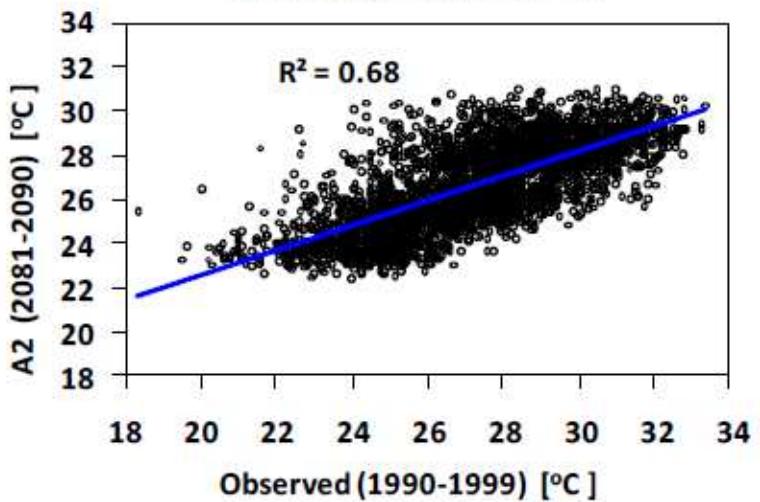

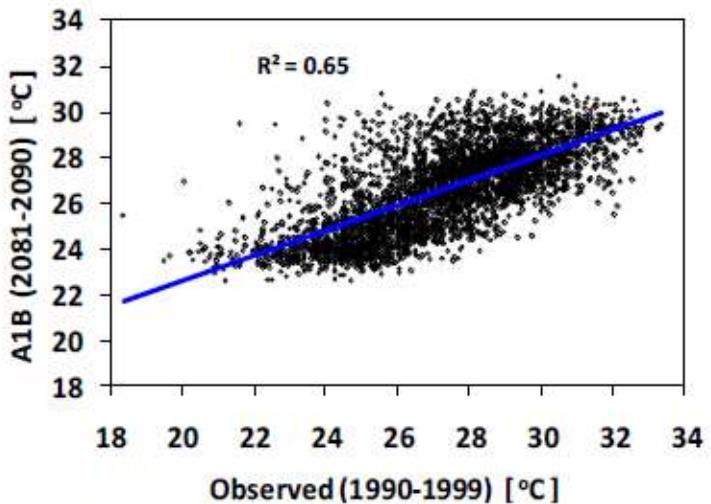

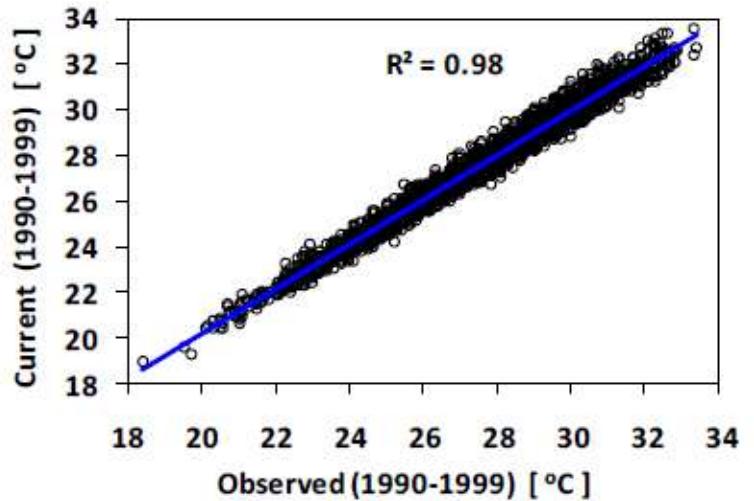

Temperature downscaling

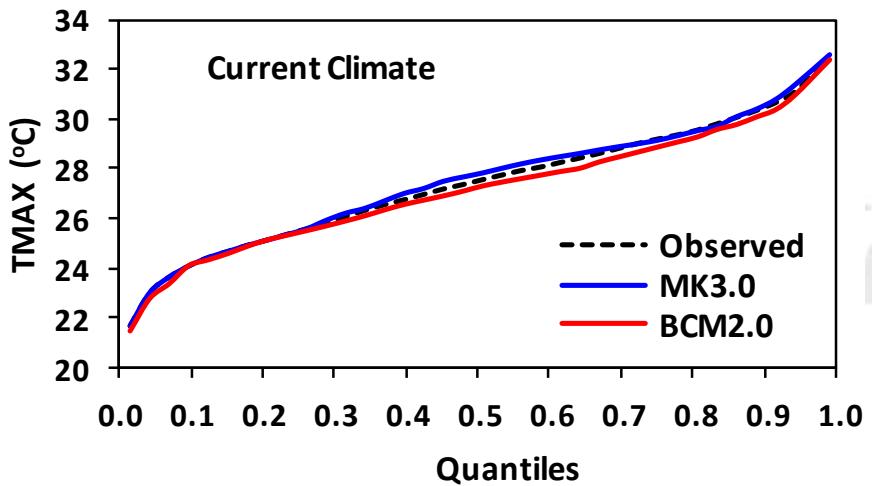

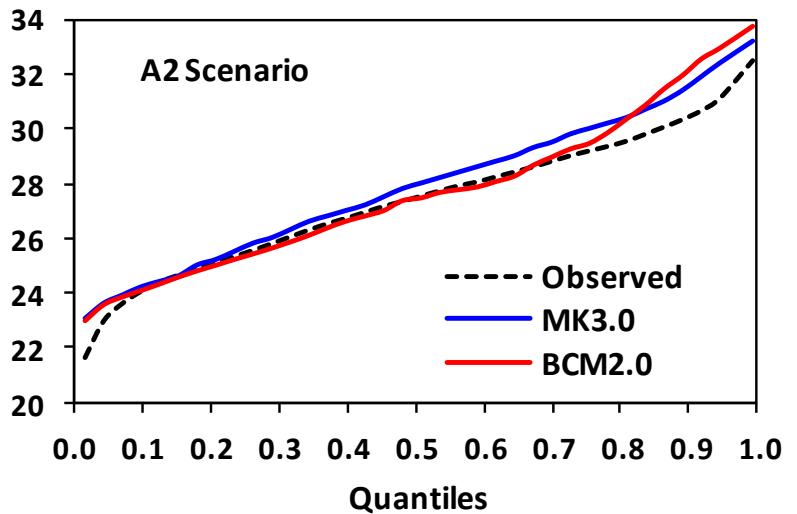

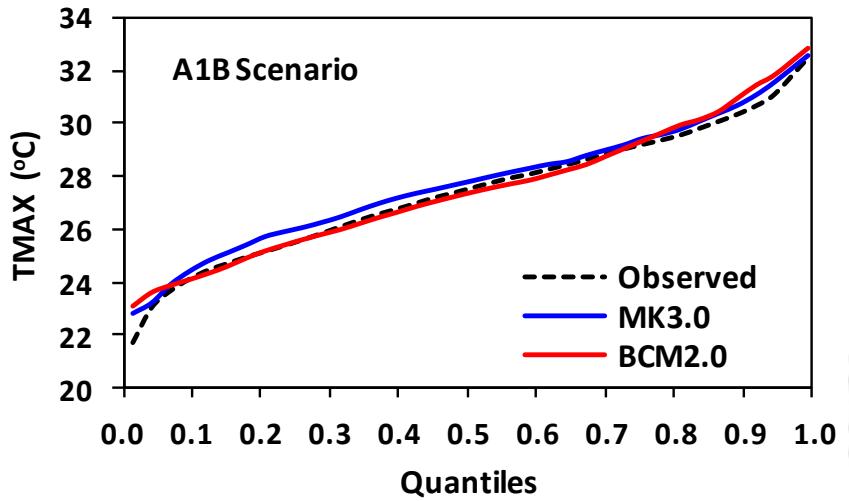

- Downscaled temperature show modest agreement to the observed series.
- Regression , quantile plot and Q-Q plot is conducted to verify the validity of simulated current climate condition.

Observed Temp. versus downscaled (Regression)

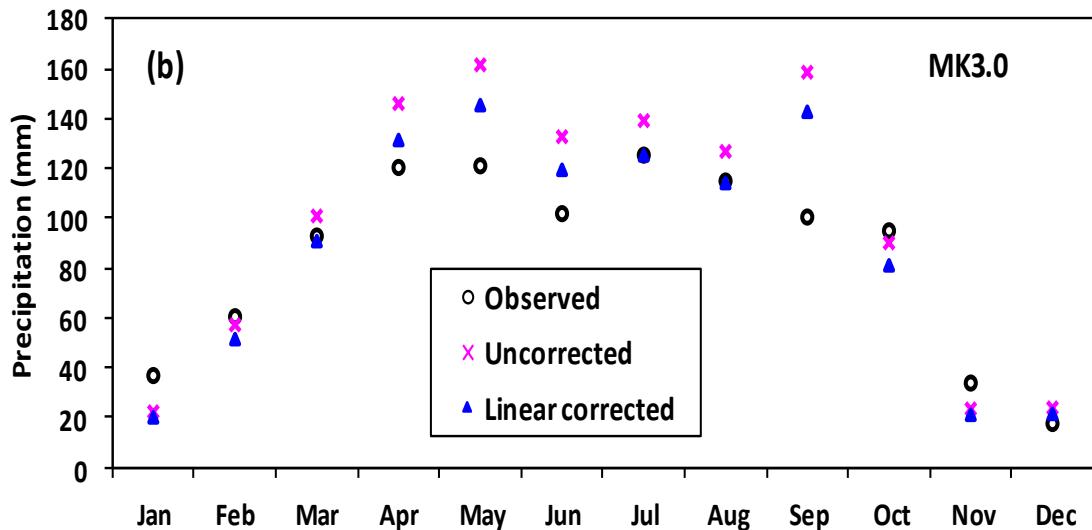

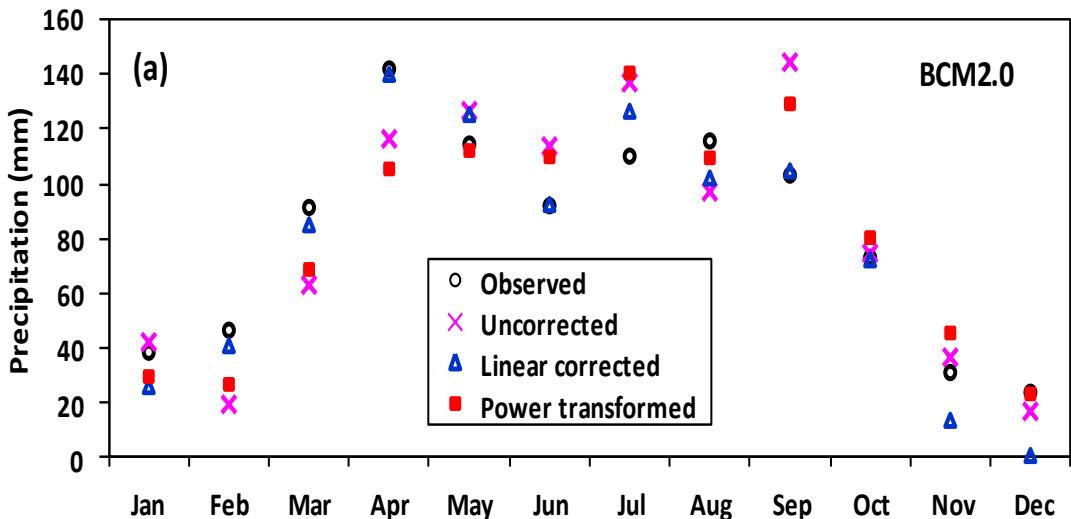

Quantile plot of temp. for two GCM realizations

The quantile plots are S-shaped and are characteristic example of bell-shaped distribution.

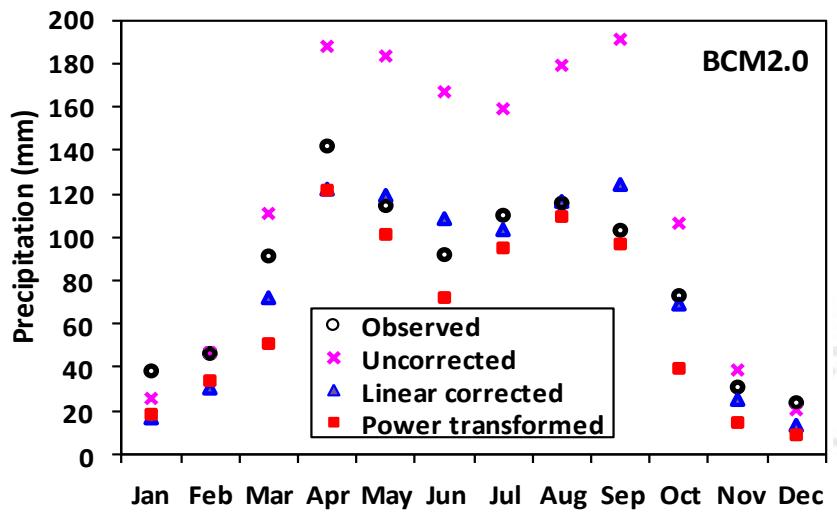

Current climate Precip. (Predicted, Observed, Bias corrected)

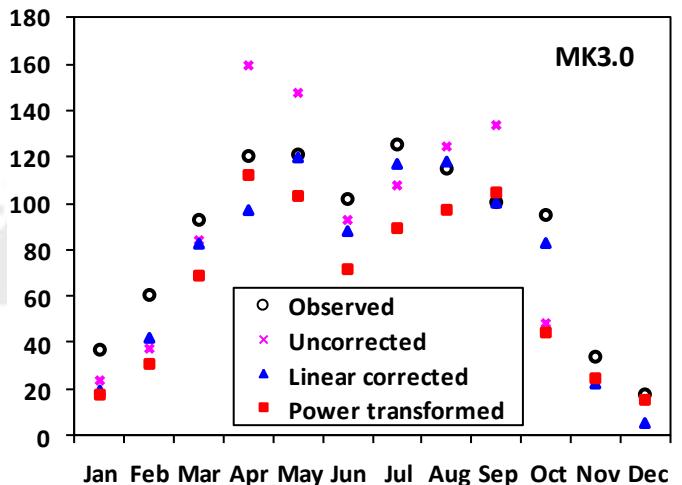

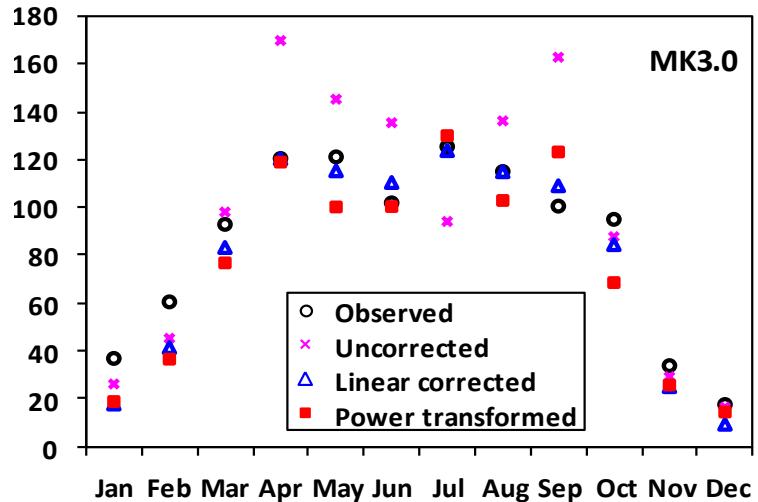

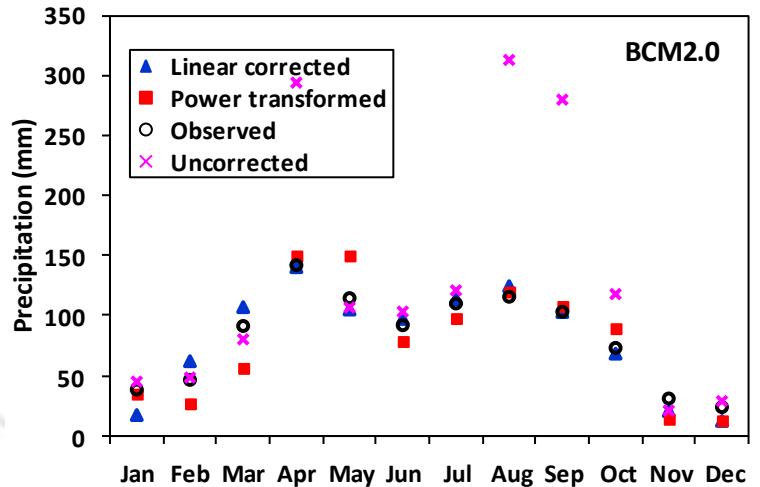

Future climate Precip. (Predicted, Observed, Bias corrected)

A1B scenario Precip.

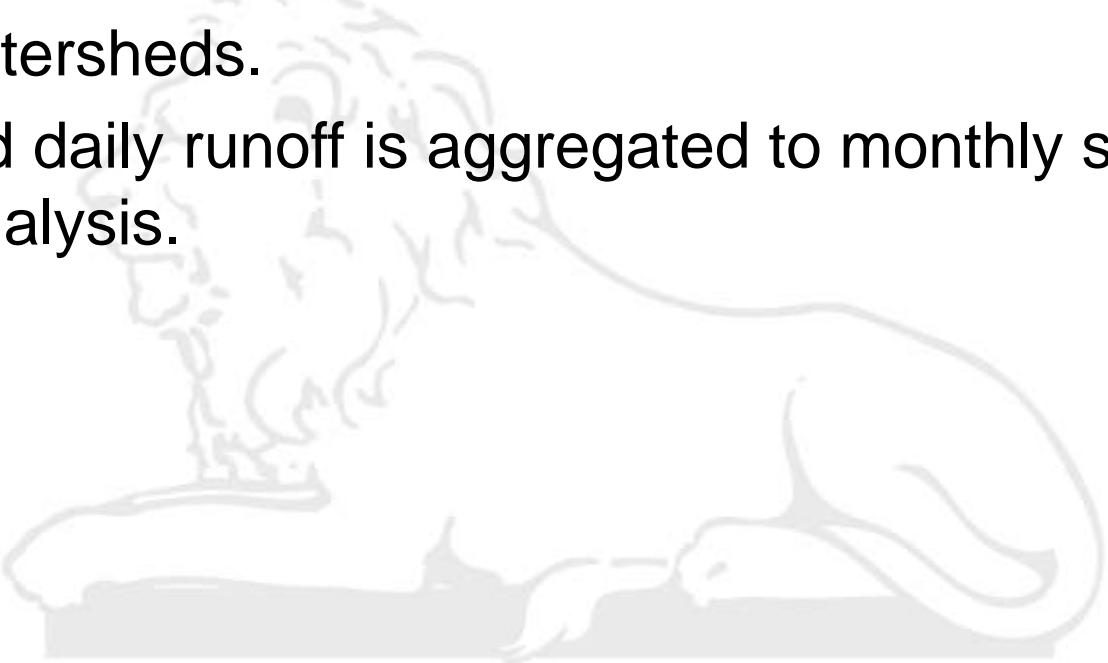

A2 scenario Precip.

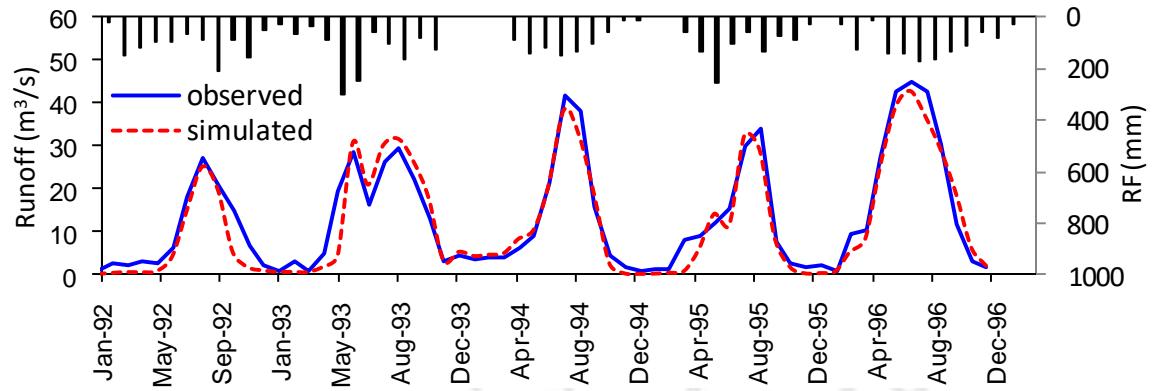

Hydrologic Modelling

- SWAT model is calibrated and validated for observed data at both watersheds.
- Runoff is simulated for current climate and future scenarios at two watersheds.
- Simulated daily runoff is aggregated to monthly series for further analysis.

Conclusion

- Runoff simulated for the **current climate** (1990-1999) using bias corrected precipitation and temperature **modestly reproduced effects similar to that of observed weather variables** at both watersheds.
- The overall NSE and coefficient of determination model performance indices ranges between 0.79 and 0.96 during calibration and validation period at both watersheds; other indices are at acceptable limit.
- The simulated annual water yield is within $\pm 3.4\%$ error to the observed annual stream flow volume at the same outlet.

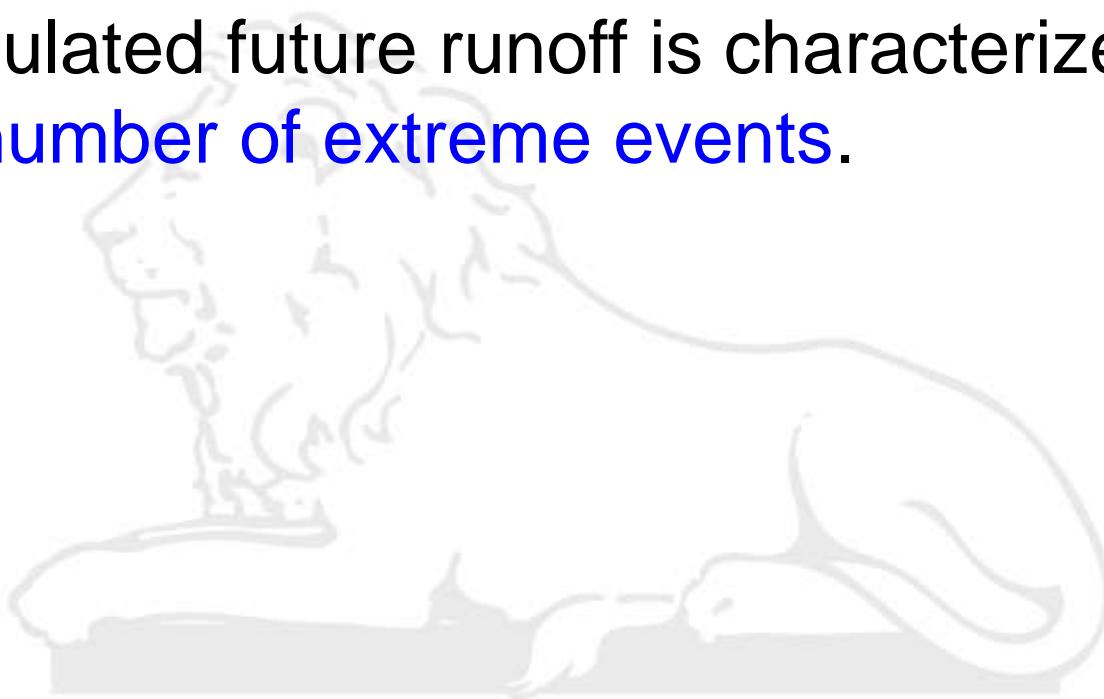

Conclusions

- Significant amount of variability is observed in downscaled precipitation for current climate whereas the associated variability for temperature is very less.
- Increased extreme precipitation and temperature events prevail for future scenarios.
- Average dry-spell length found to increase between October and February whereas it remains stable from March – September months for both emission scenarios.
- Bias correction improved both the mean and CV to a reasonable degree

Conclusions...

- Simulated average annual water yield shows slight variation between GCMs.
- The simulated future runoff is characterized by higher number of extreme events.
