

Land use planning methodology to improve the regulation of the hydrological cycle

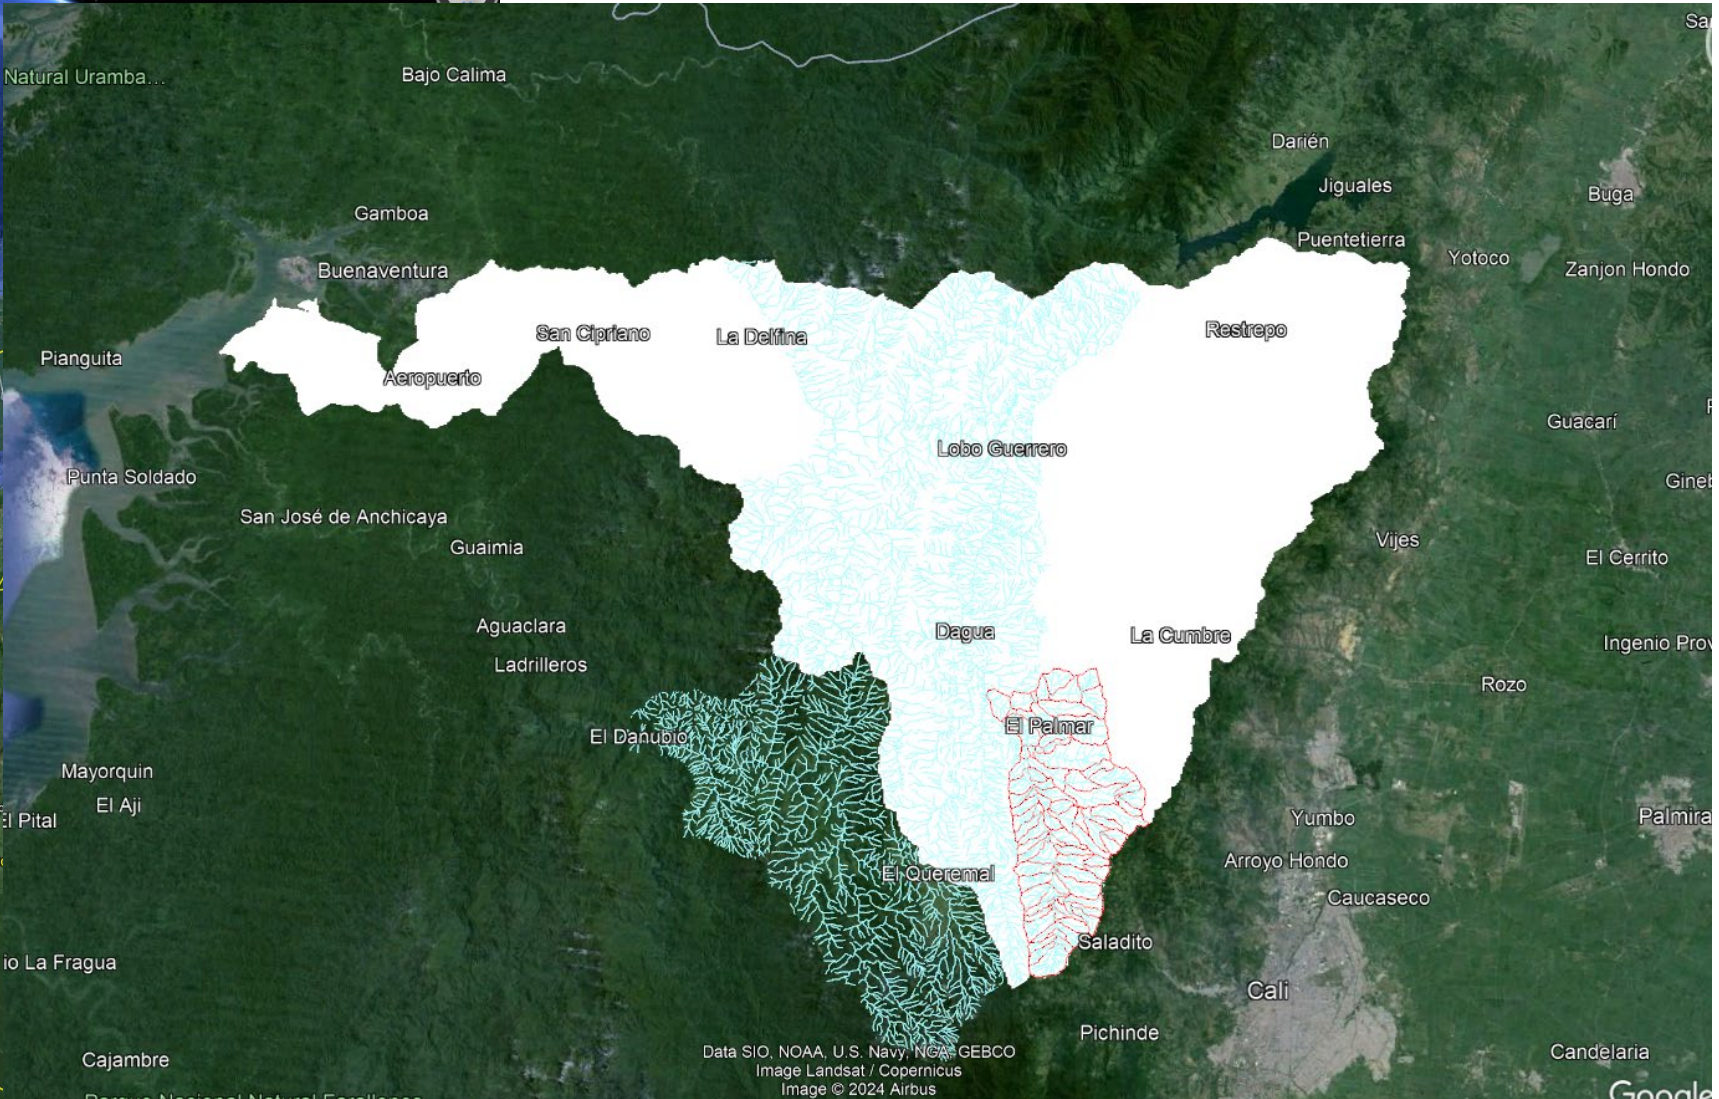

Diana Hincapié, PhD (c)

Environmental – Risk management consultant

Content

1. The problem: exposing the case of Dagua – Valle del Cauca.
2. Context of landscape planning in the municipality of Dagua
3. Landscape planning, ecological process, and ecosystem services for Dagua
4. The experiment...
5. Results
6. Conclusions

Environmental determinants

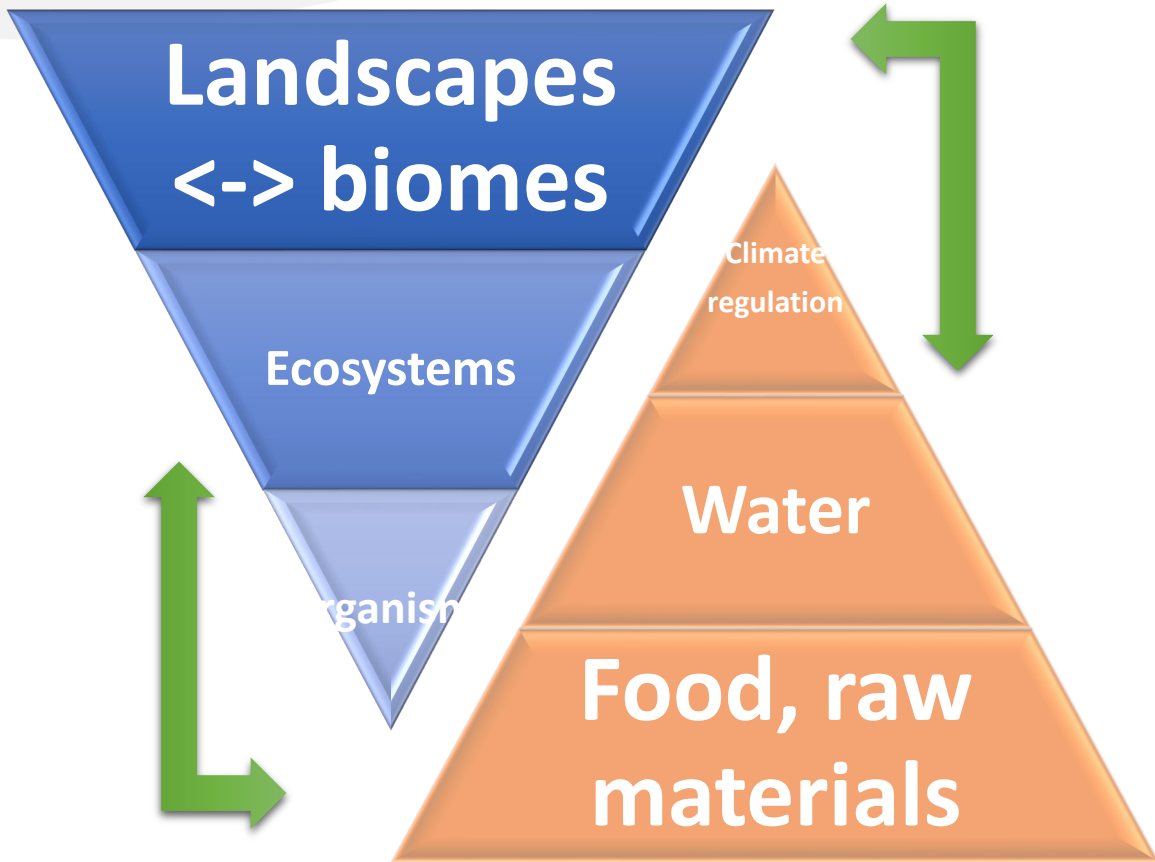

- It is a category of soil protection imposed by the environmental authority.
- Dagua has a category all over its territory → soil protected by the second law from 1959.
- Under this legal act, the municipality is not able to execute sanitation projects in consequence there are several environmental problems related with water pollution.
- To solve this, landscape planning must be done.

2. The context of landscape planning

- How do we occupy biophysical space?
- How much respect do we have for the flora and fauna species of that space?
- Can we know the impact that these space occupation decisions have in terms of the impact on human requirements such as the amount of water?

3. Landscape planning, ecological process, and ecosystem services

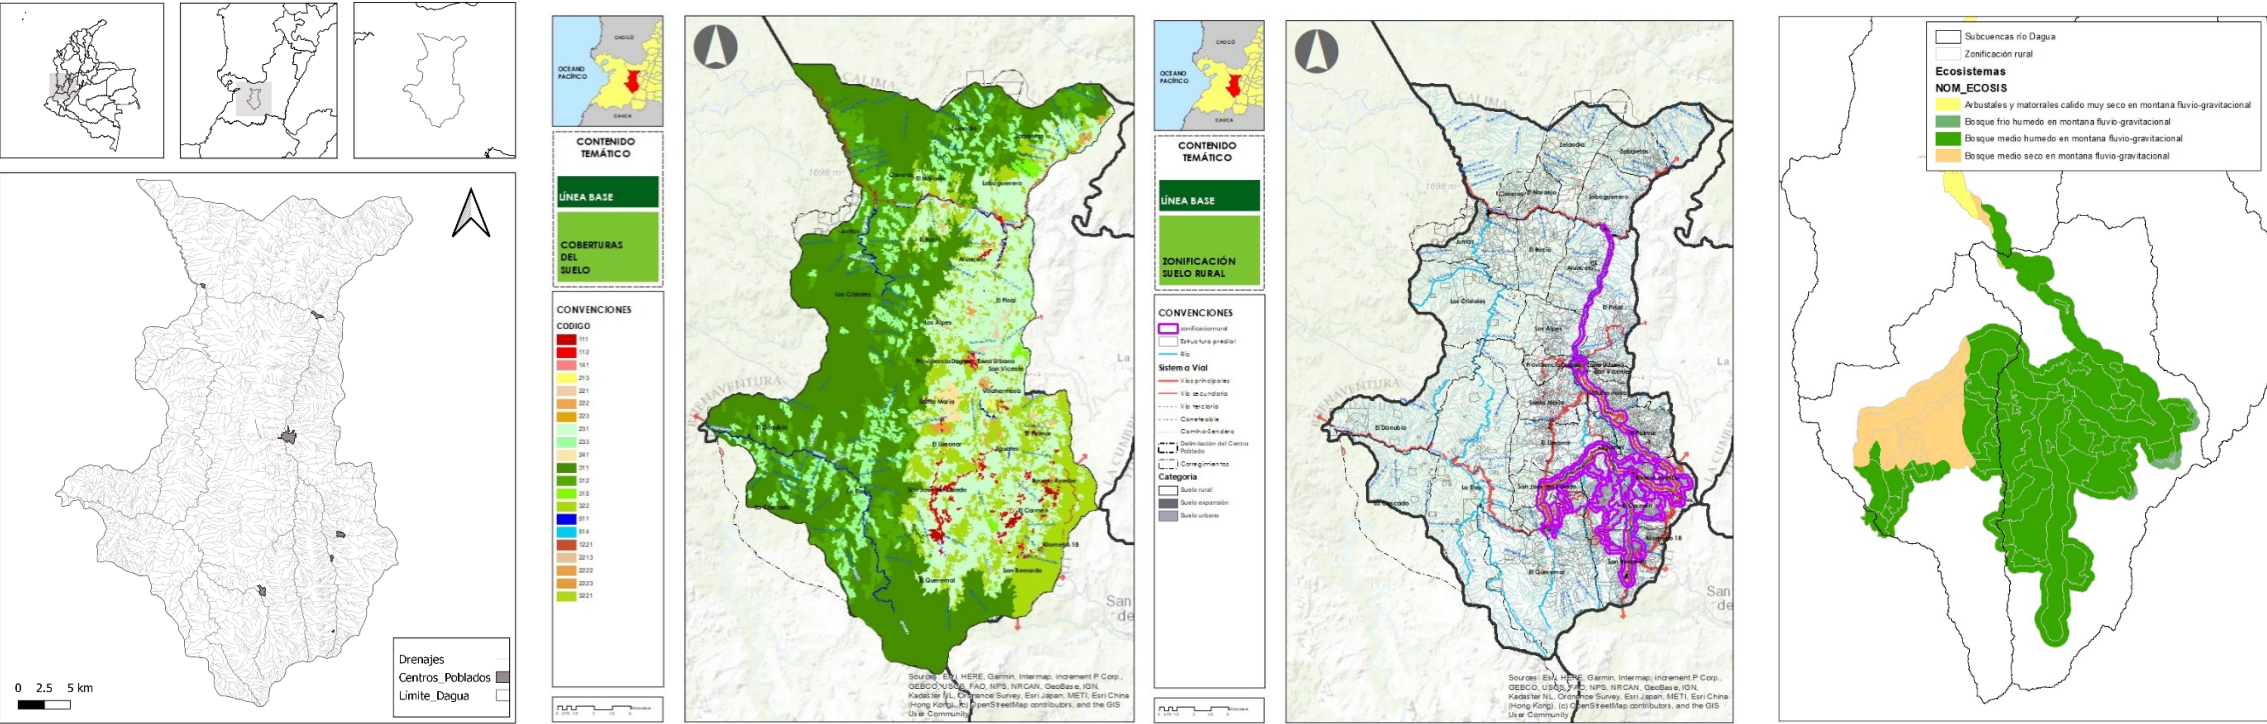

But... we need to make decisions right now..

Landscape level → minimum 20 years...

To understand ecological process at this level requires a specialized tool

1. Working scale
2. Type of experiments that we can perform
3. Time of experiments

4. The experiment...(methodology)

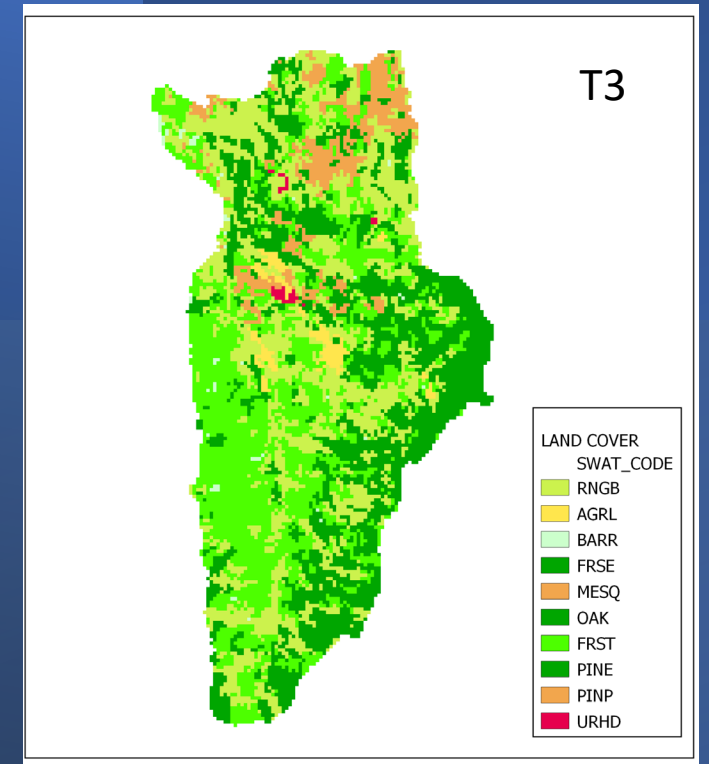

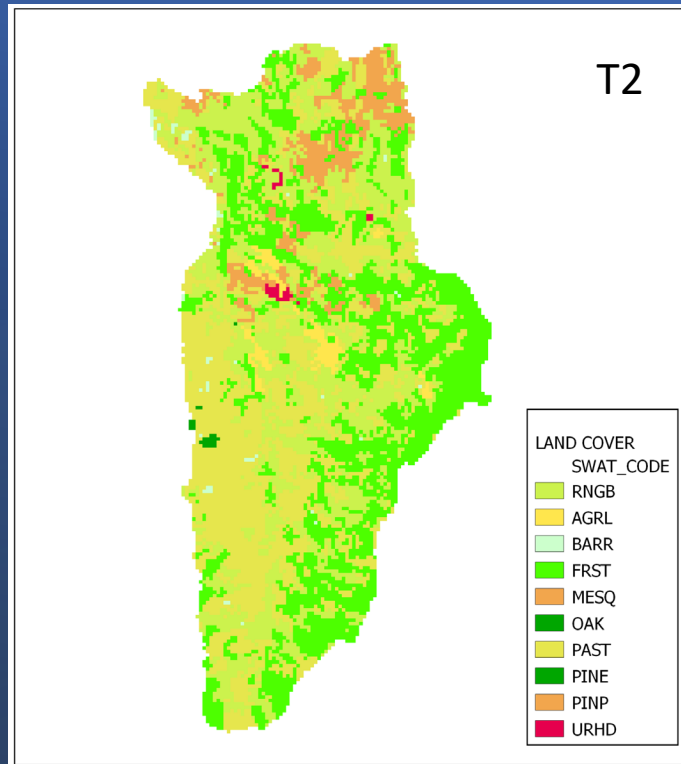

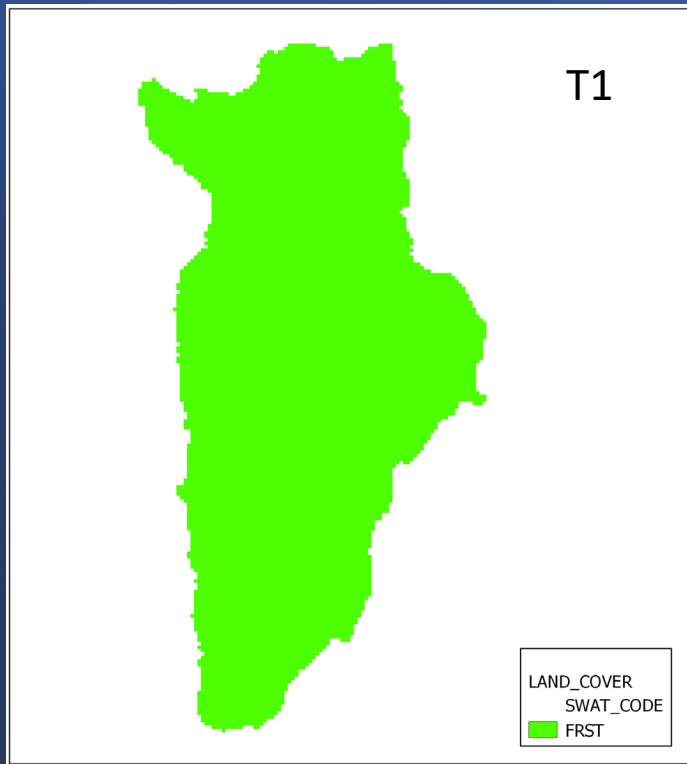

Where do we invest the money, on what areas?

Inputs

- DEM → 2.5 m given by the environmental authority.
- Hydrological soil map → developed by the environmental authority, 1:25.000 – semi-detailed → adjusted lookup tables to usersoils
- Land use/land cover map → obtained by the municipality, 1:25.000
- Climate data: obtained from SWAT climate databases, monthly values were adjusted from national measures, only for precipitation and temperature.

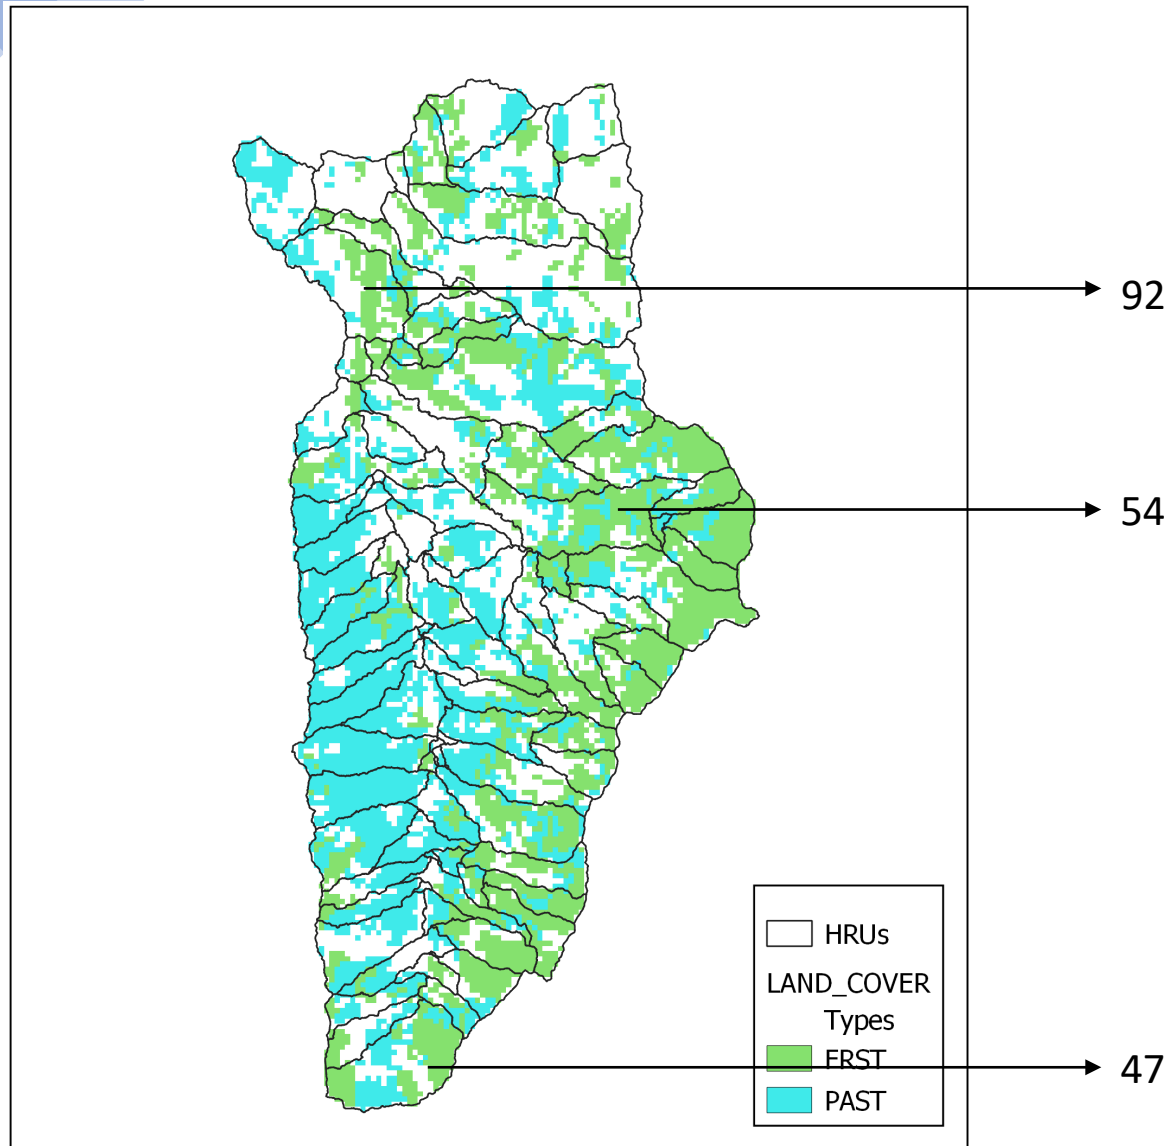

Class	Landscape Proportion
FRST	100.0%

Class	%	Ha
RNGB	17.0%	2978.6
AGRL	1.0%	178.5
BARR	0.3%	54.8
FRST	18.0%	3145.6
MESQ	3.6%	634.4
OAK	0.1%	21.2
PAST	18.7%	3272.9
PINE	0.0%	0.9
PINP	0.2%	33.6
URHD	0.2%	34.5

Class	Landscape Proportion	Column1
RNGB	17.0%	2978.6
AGRL	1.0%	178.5
BARR	0.3%	54.8
FRSE	18.0%	3145.6
MESQ	3.6%	634.4
OAK	0.1%	21.2
FRST	18.7%	3272.9
PINE	0.0%	0.9
PINP	0.2%	33.6
URHD	0.2%	34.5

WB – Et/Sr - Sed

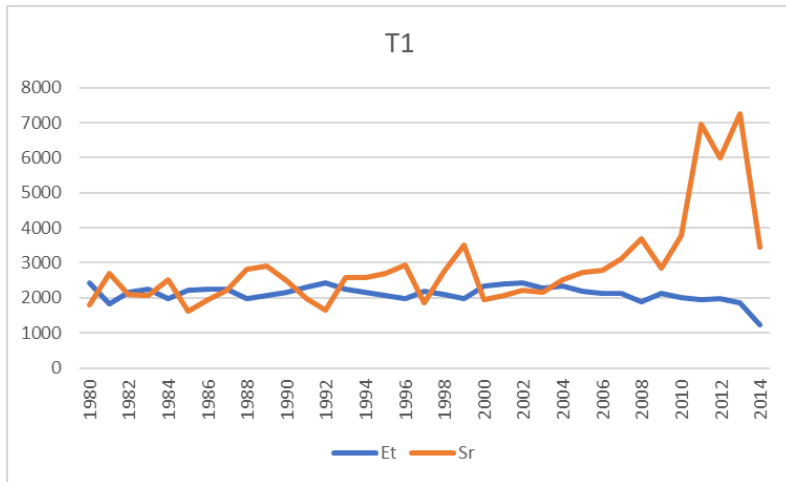

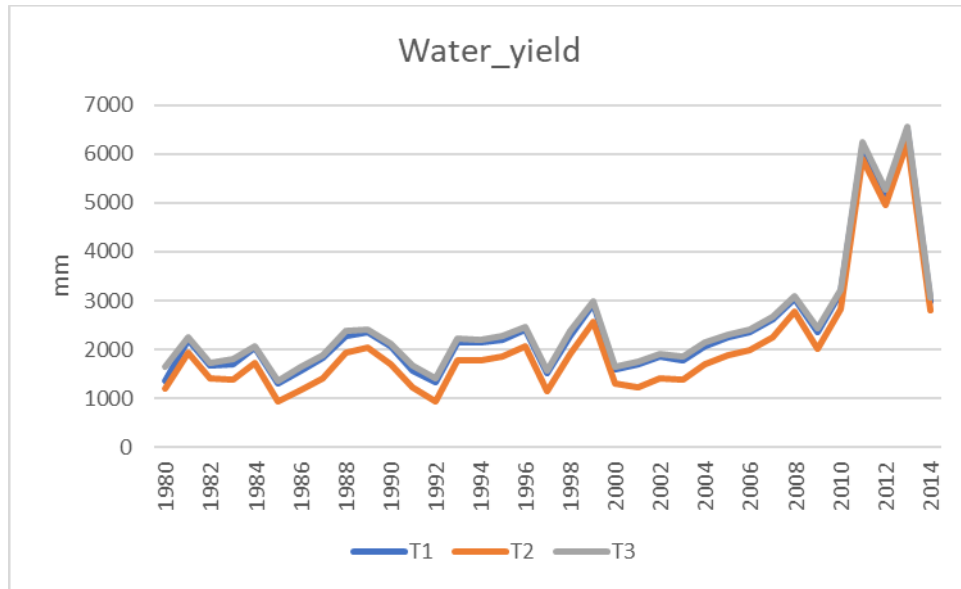

Comparison between series of water yields on each treatment for each HRU picked

Relation between evapotranspiration and superficial run-off

Quantity of sediments reduced by each treatment

5. Results

6. Conclusions and recommendations

Conclusions

- It is a preview of a bigger project
- The treatments show the effectiveness of the decision towards land cover management
- It is the baseline for economic decisions
- The results show where to do the investments and execute the actions of vegetation recover
- Dagua can generate the strategy to recover land cover using agroecological systems
- Also, the project it useful to implement early warning system

Recommendations

- The model must be calibrated
- Measurements of flow and sediments are needed to calibrate the model
- Research on values of water intake due to plants must be done, because of the tropical conditions. That must be pply for hydrological soil map, as well

What's next?

- To automatize the method to assess the specific areas where sediments are reduced.
- To prove another configurations of land cover recover...

For your attention, thank you so
much!
